Introducción a Python para Científicos

Ramon Crehuet
https://ramoncrehuet.wordpress.com/
https://twitter.com/rcrehuet

Barcelona, marzo 2019

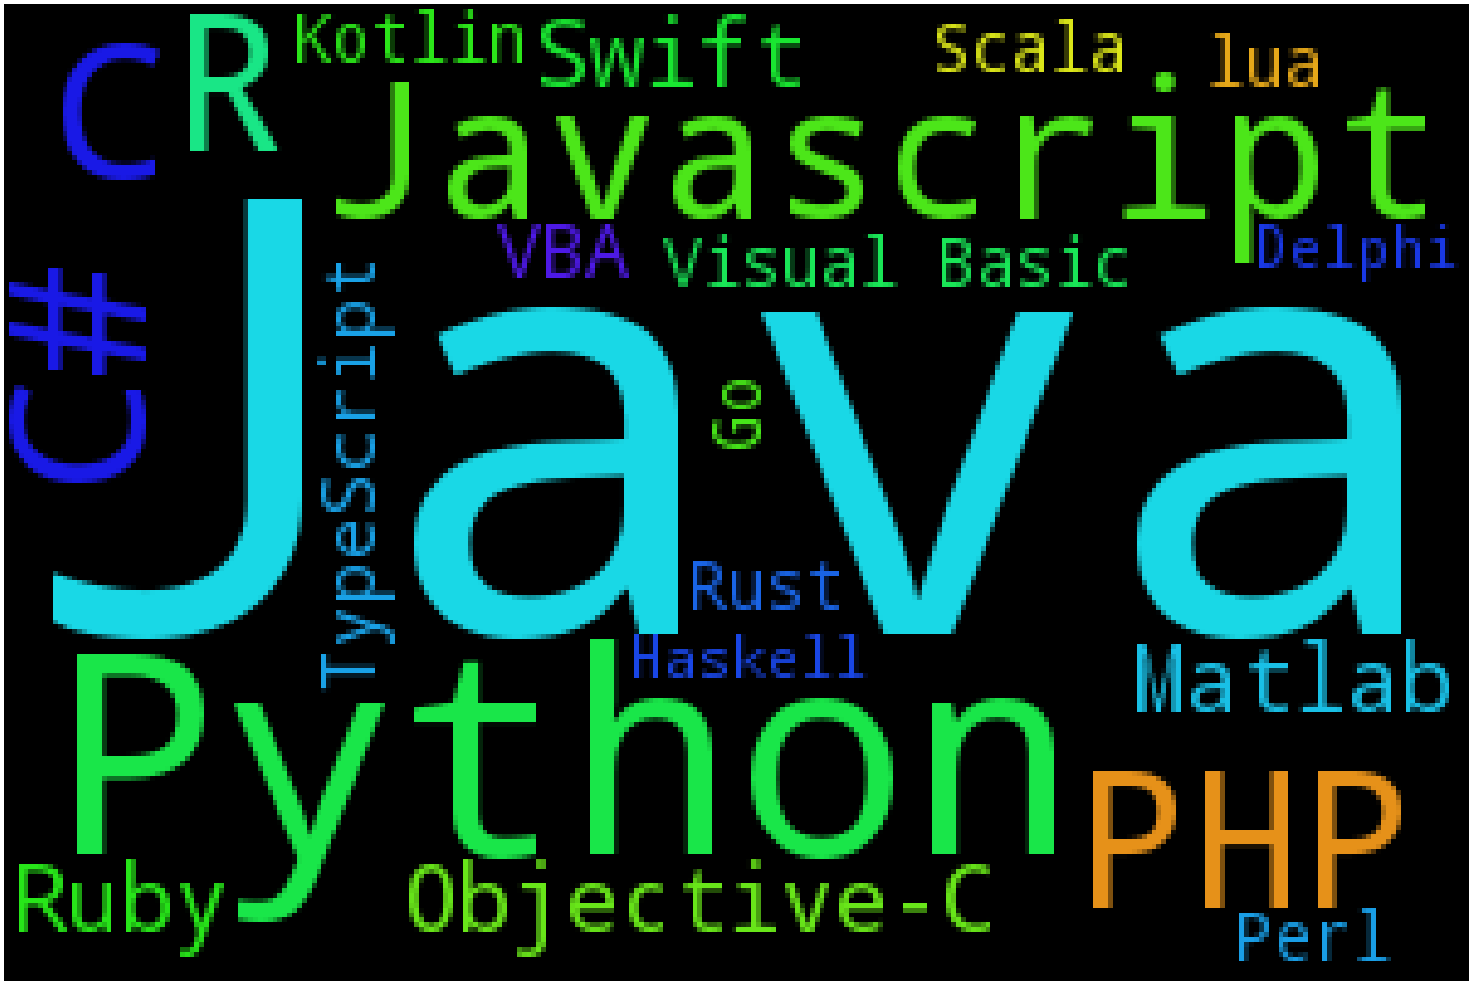
You?

- Research institute?
- Research field?
- Known languages?
- Kind of data?
- Expectations?

Overview

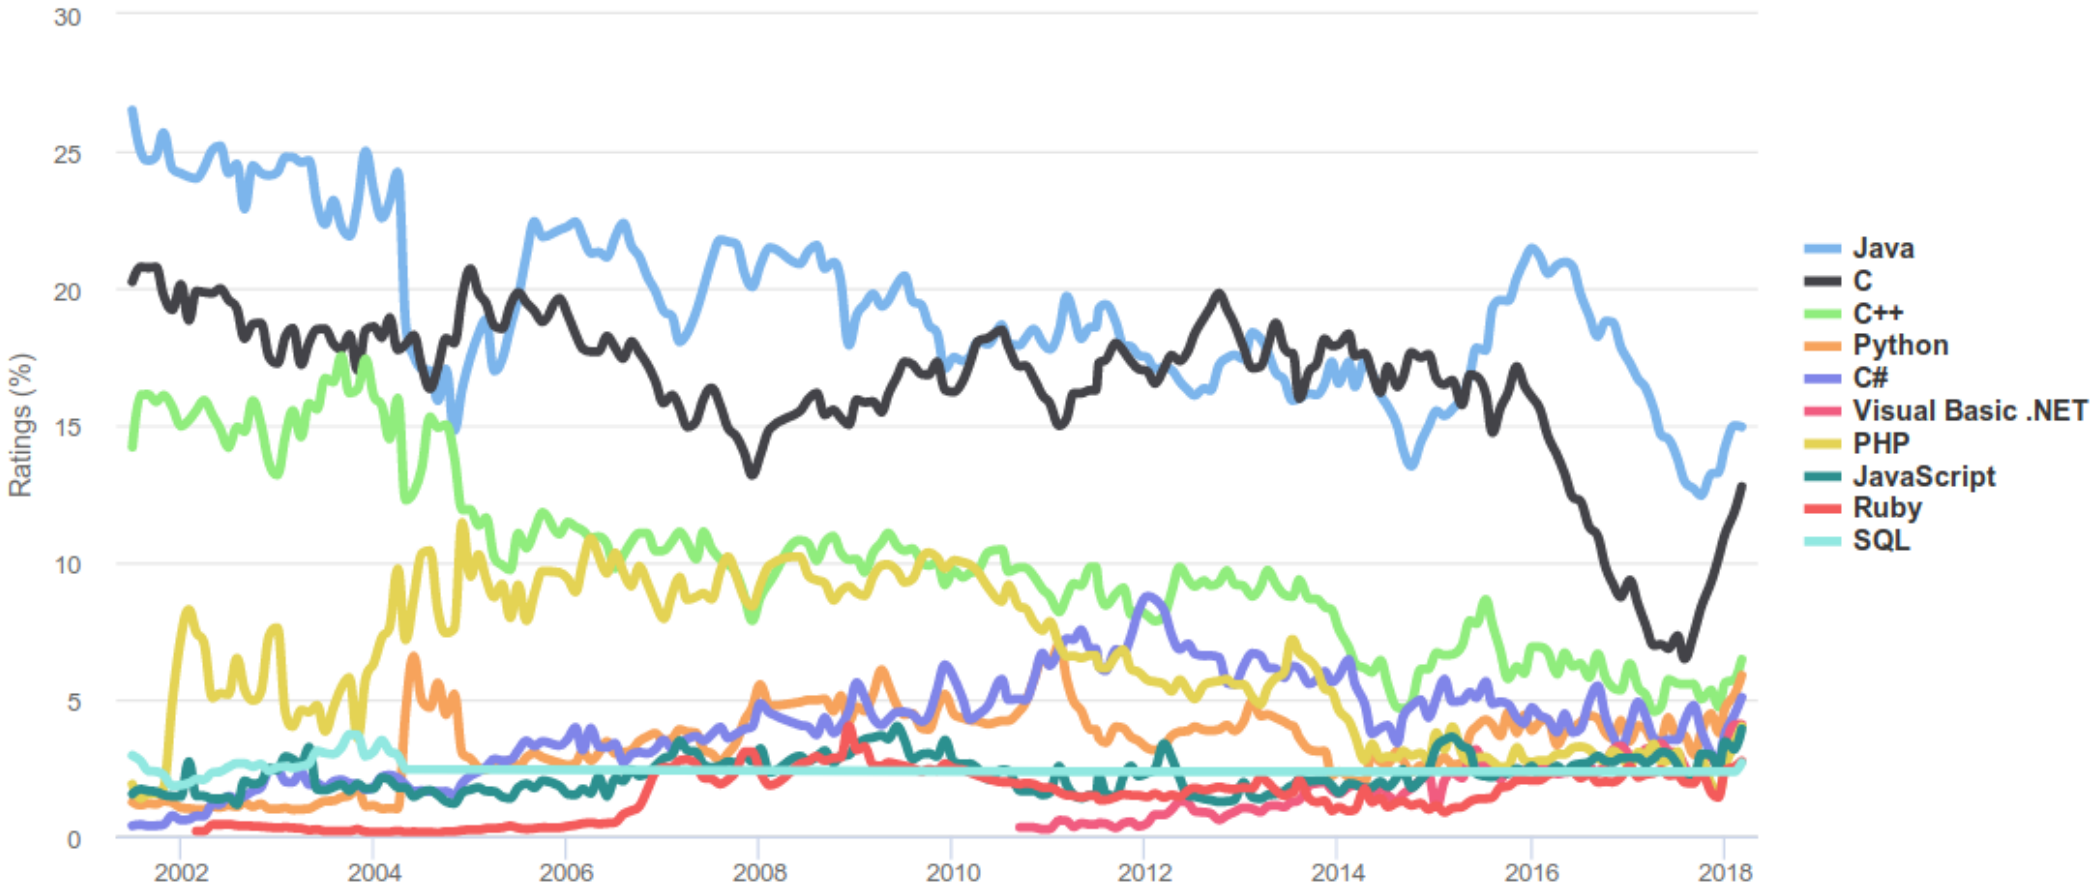
- Why Python
- Language basics
- Working with files
- Working with arrays: Numpy
- Data visualization: matplotlib
- Functions and modules
- Scientific modules. Scipy
- Classes and objects (bare minimum!)
- Other scientific modules: sckikit-learn, biopython...
- Profiling and optimization and beyond Python

Language popularity



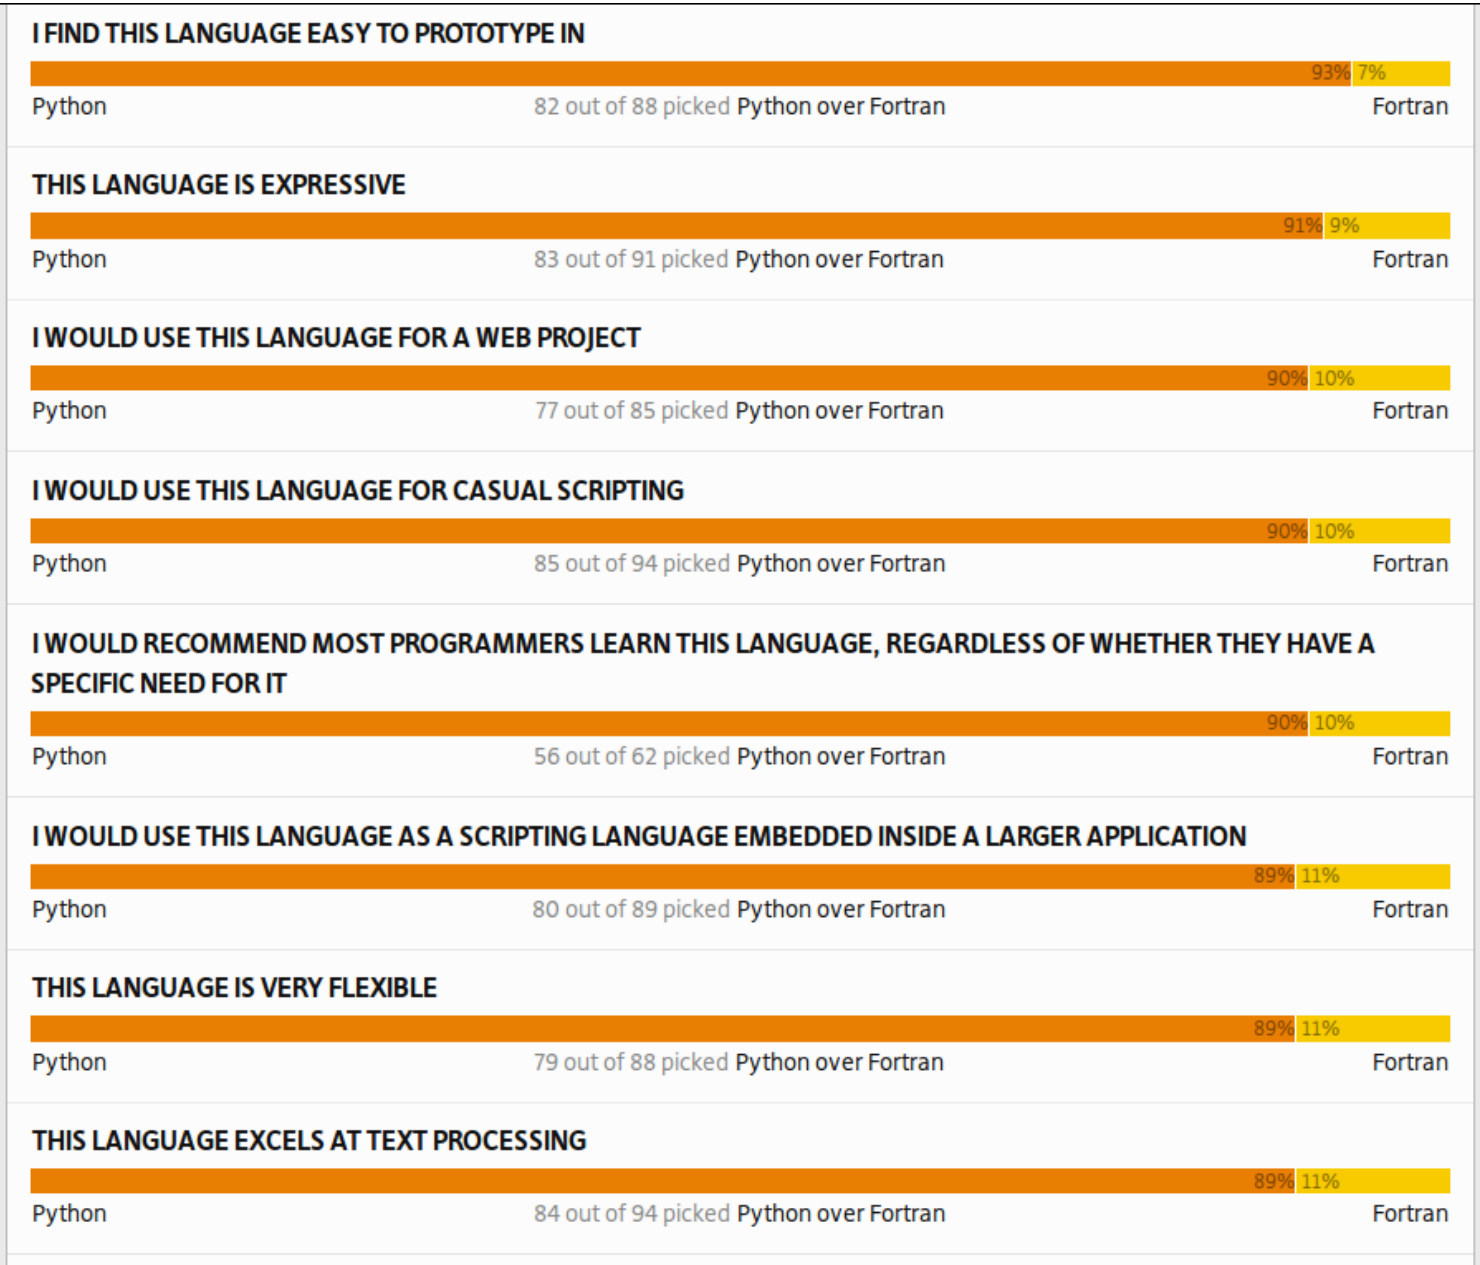
http://pypl.github.io/PYPL.html

Language popularity



http://www.tiobe.com/index.php/content/paperinfo/tpci/index.html

Hammerprinciple.com



Python for science

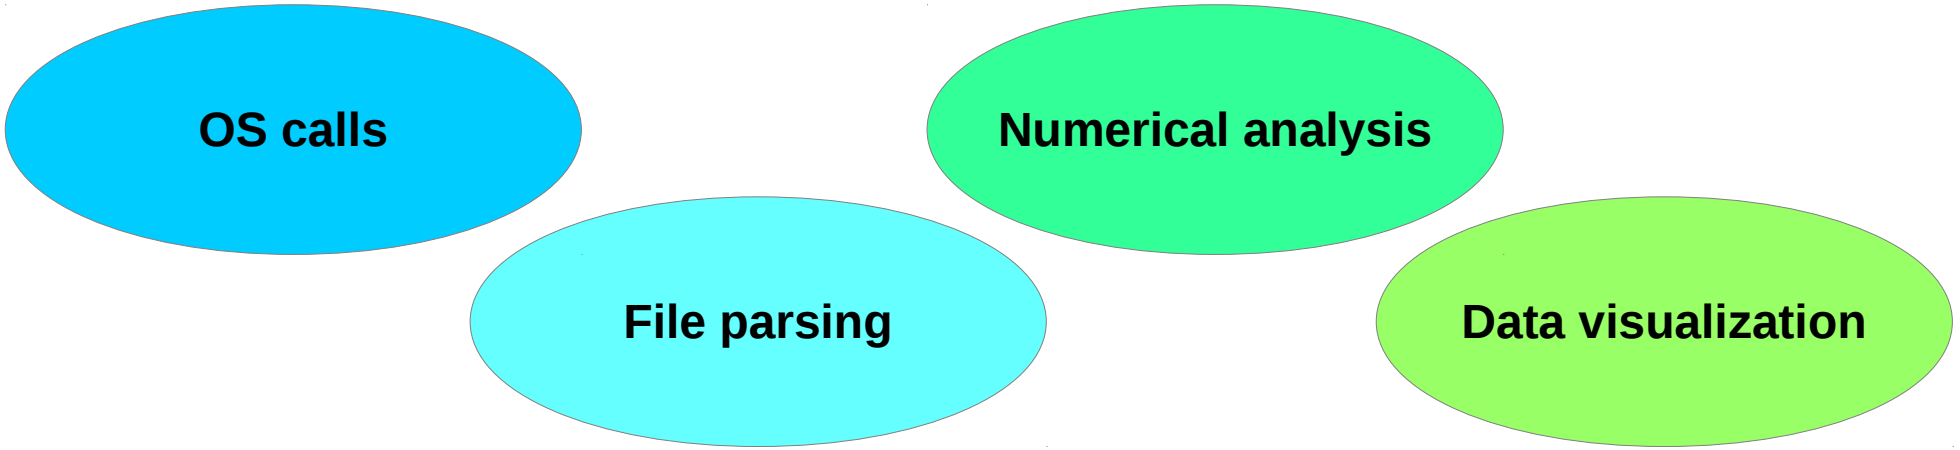
- A high level language gives more time to more complex problems
  - At the expense of hiding important details
- Example:
  - A reaction mechanism
  - Optimisation of an energy function
    - Steepest descent, conjugate gradients, quasi-Newton
  - Implementation of BFGS quasi-Newton
    - Memory issues, diagonalization, matrix inversion...
  - Calculation of numerical gradients or hessians:
    - machine precision, central differences, etc.

http://fperez.org/py4science/why_python.html

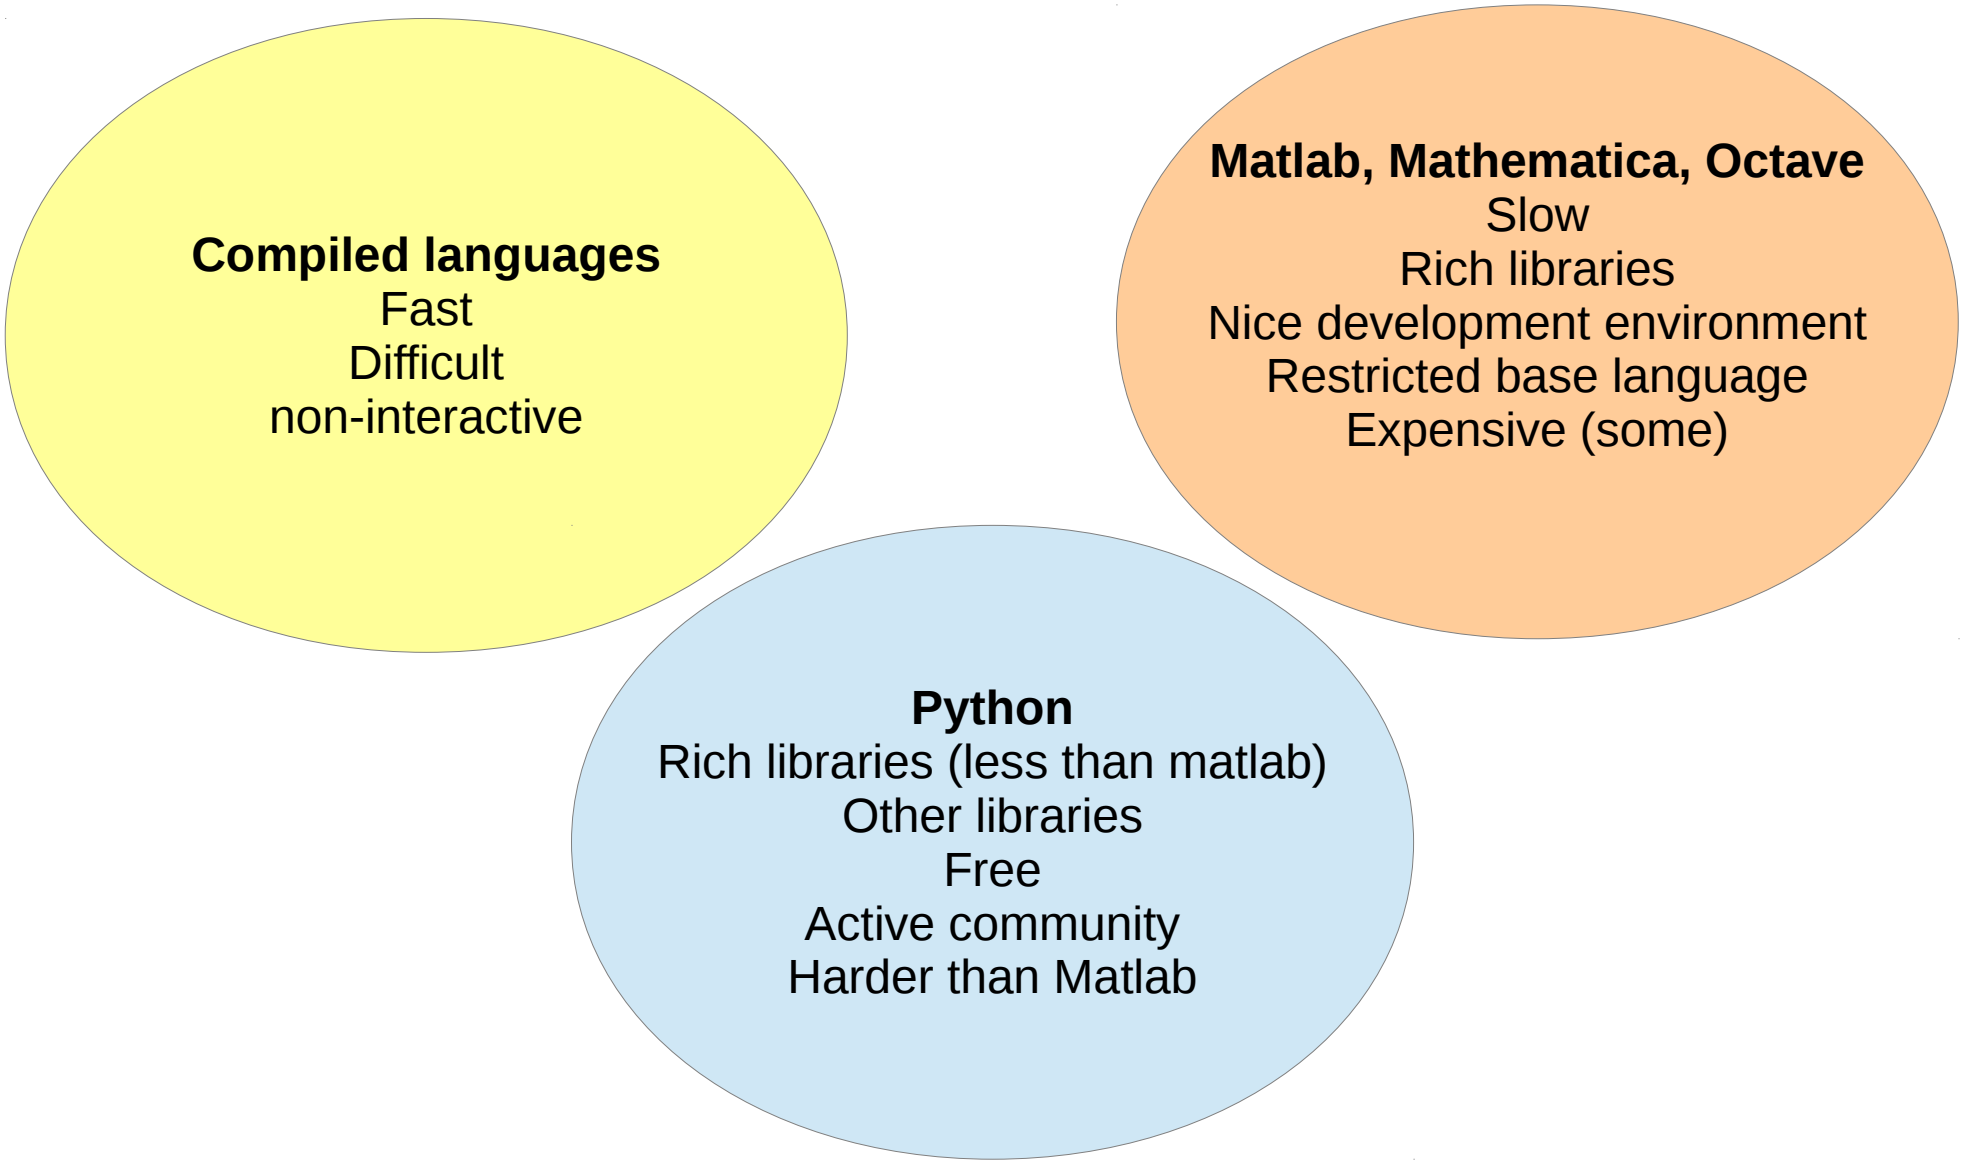
Python for science

“We then generated 1000 random sequences with randomly specified 〈H〉 and 〈Q〉 values, and conducted molecular-dynamics simulations to calculate the 〈Rg〉 for each chain. The obtained 〈Rg〉 values were combined with the two-state formalism to determine whether the chain was ordered (globule) or disordered (coil)”

Biophysical Journal, **104**, 2013, 488–495



Python for science

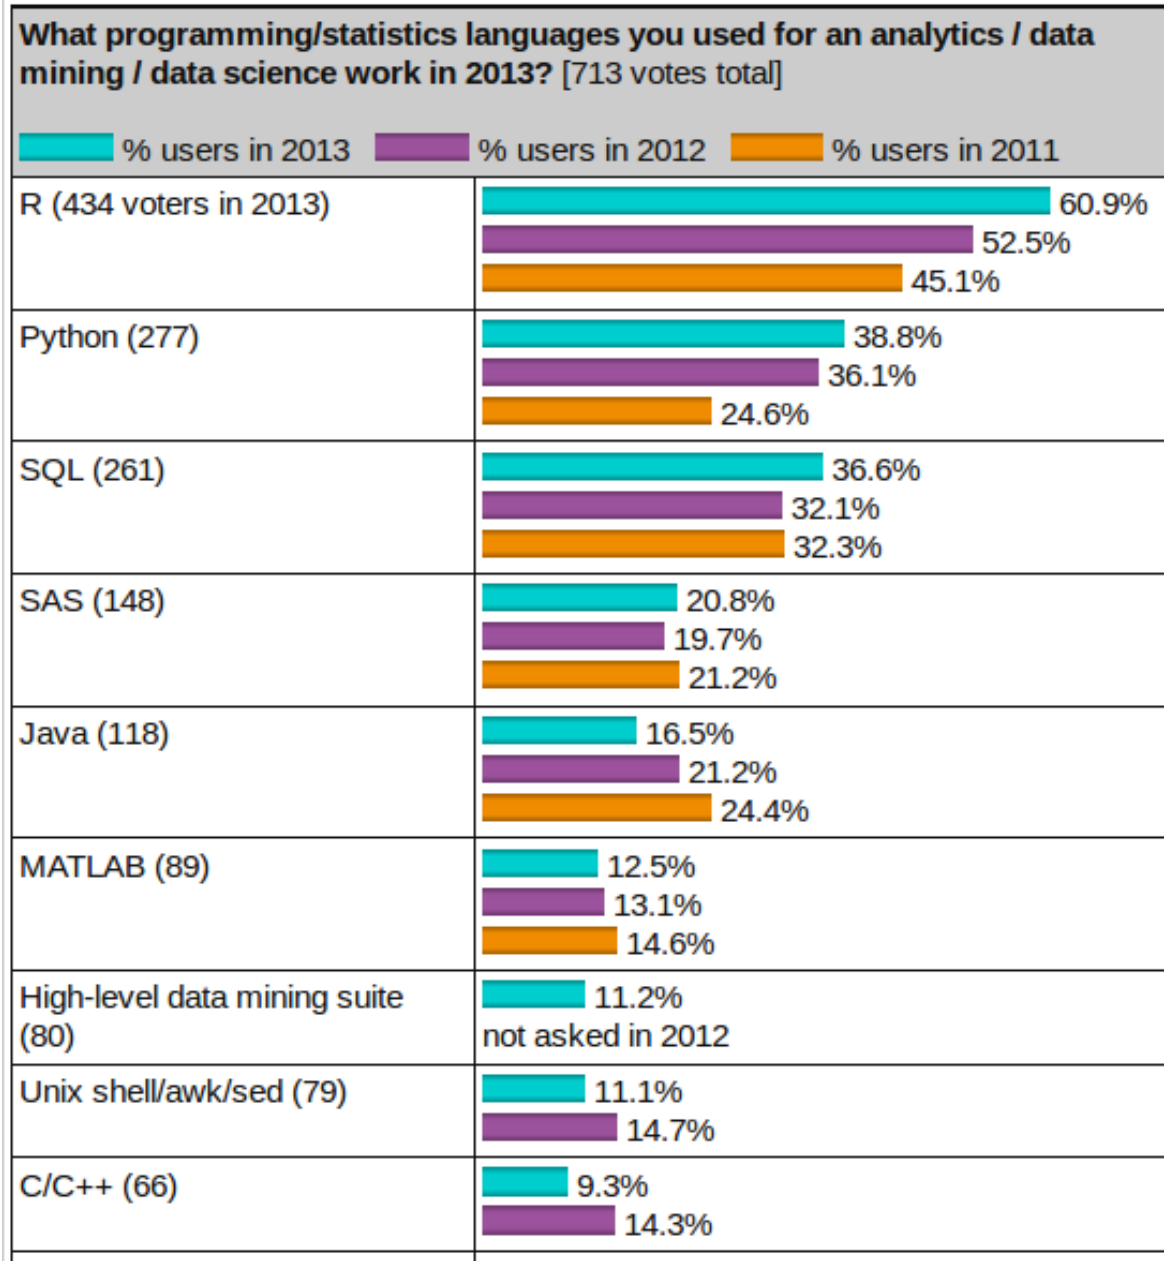


Matlab, Mathematica?

- Scientific computing:
  - ipython + scipy + matplotlib
- Free
- Open source
- Extensible

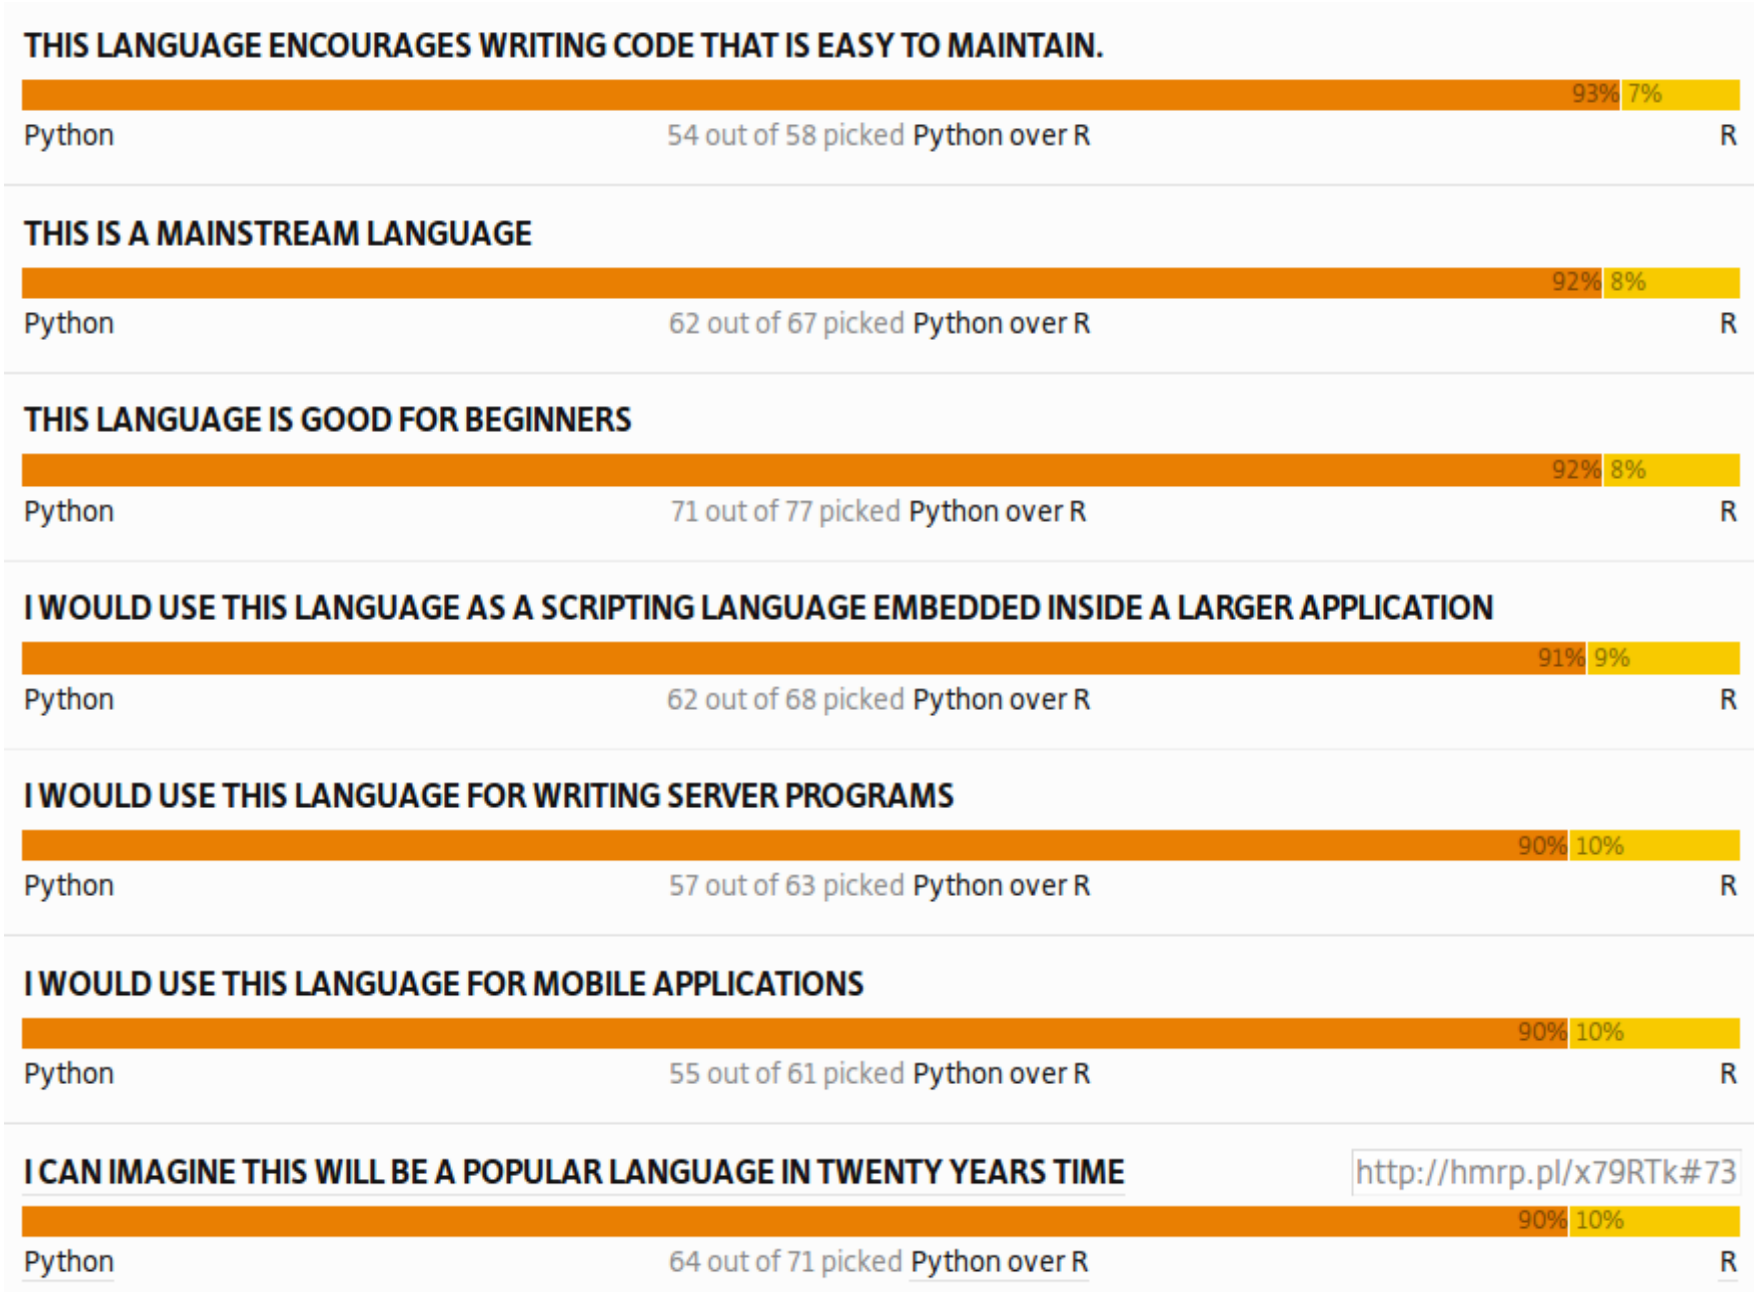
- Bioinformatics
  - Biopython
- Molecular Dynamics
  - MMTK
- Efficiency
  - Numba, Cython, Fortran, C
- Server control
- XML parser

Python for data science

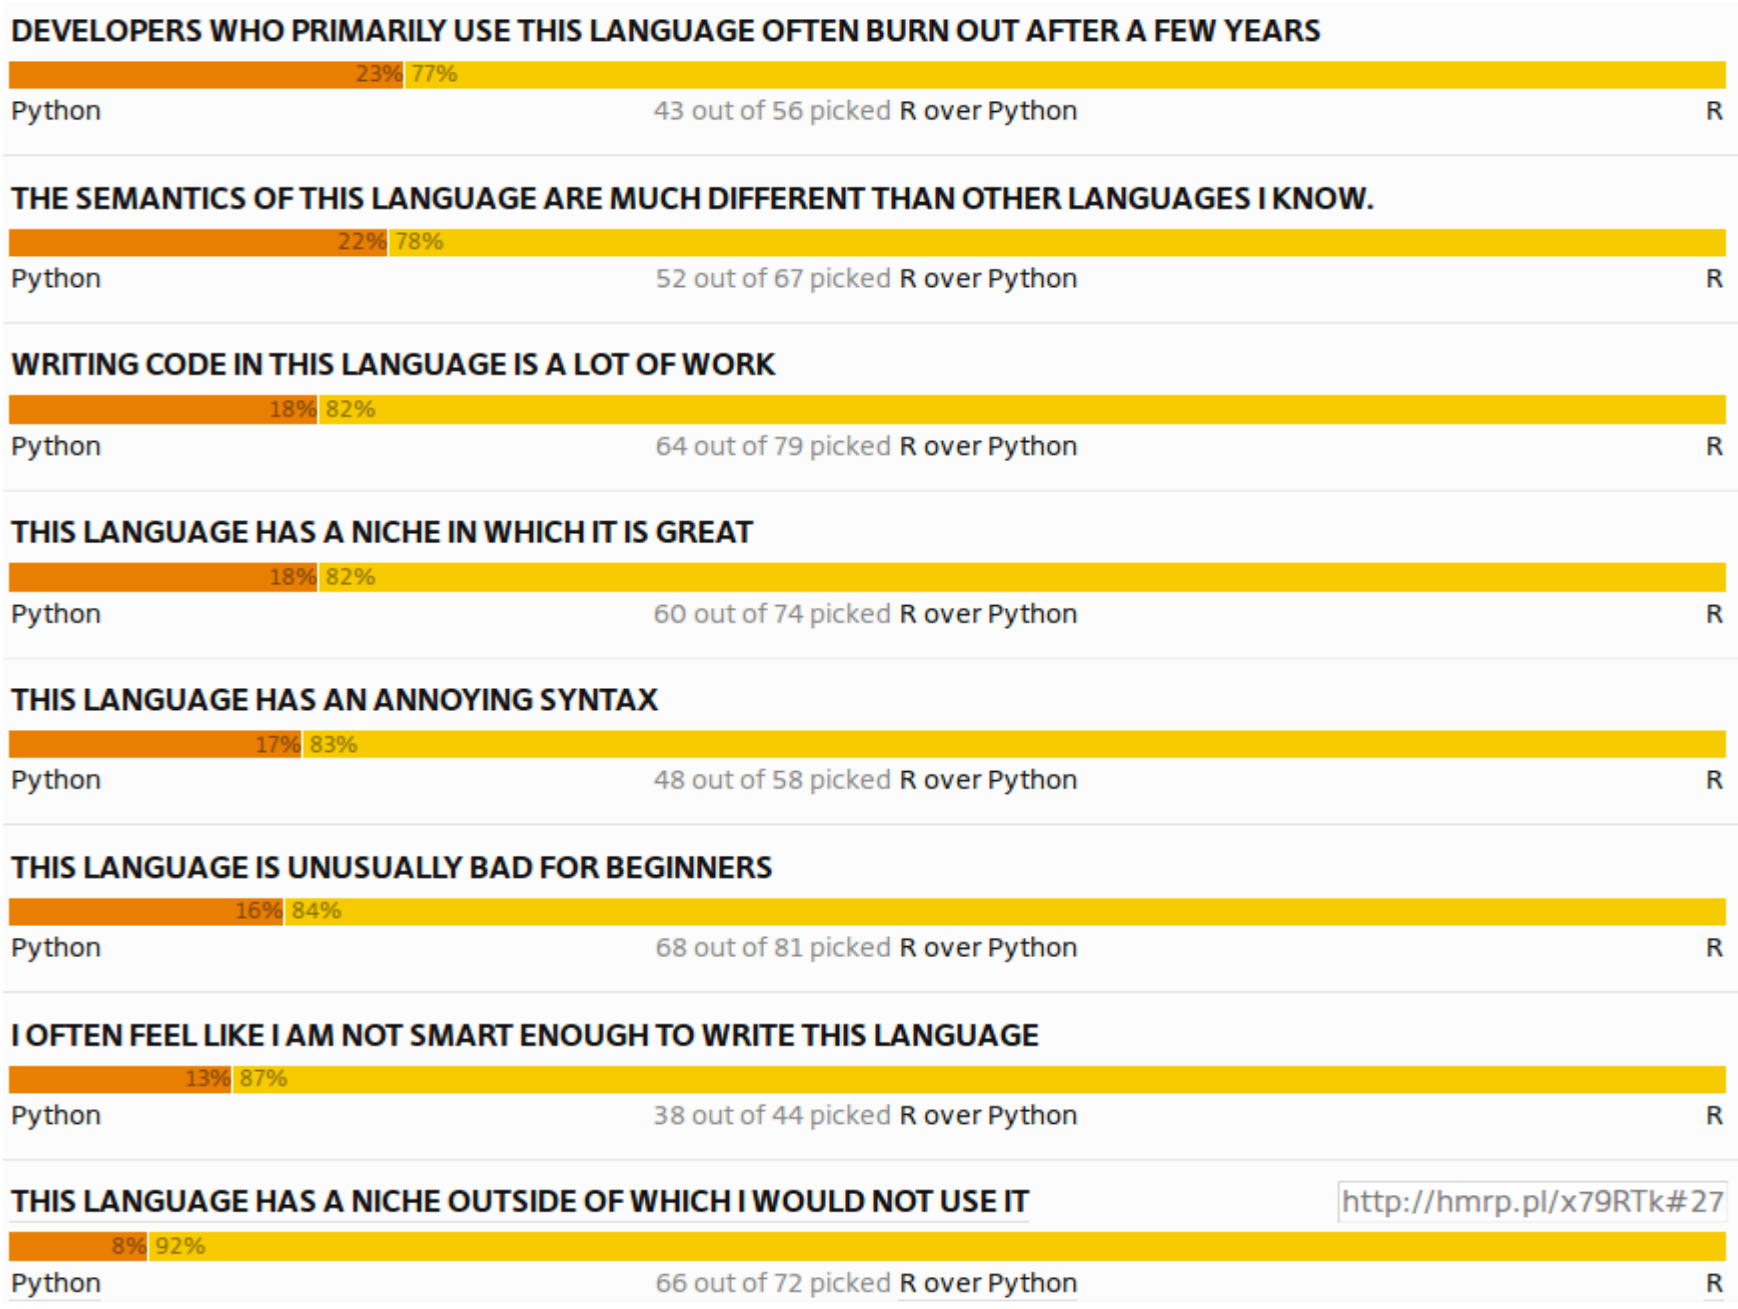


http://www.kdnuggets.com/2013/08/languages-for-analytics-data-mining-data-science.html

Hammerprinciple.com



Hammerprinciple.com



Python for data science

- Which is better for data analysis: R or Python?
  http://www.quora.com/Which-is-better-for-data-analysis-R-or-Python
- SAS vs. R (vs. Python) – which tool should I learn?
  http://www.analyticsvidhya.com/blog/2014/03/sas-vs-vs-python-tool-learn/
- Python Vs R Machine learning
  http://datascience.stackexchange.com/questions/326/python-vs-r-machine-learning
- How to Choose Between Learning Python or R First
  http://blog.udacity.com/2015/01/python-vs-r-learn-first.html
- Python, Machine Learning, and Language Wars
  http://sebastianraschka.com/blog/2015/why-python.html

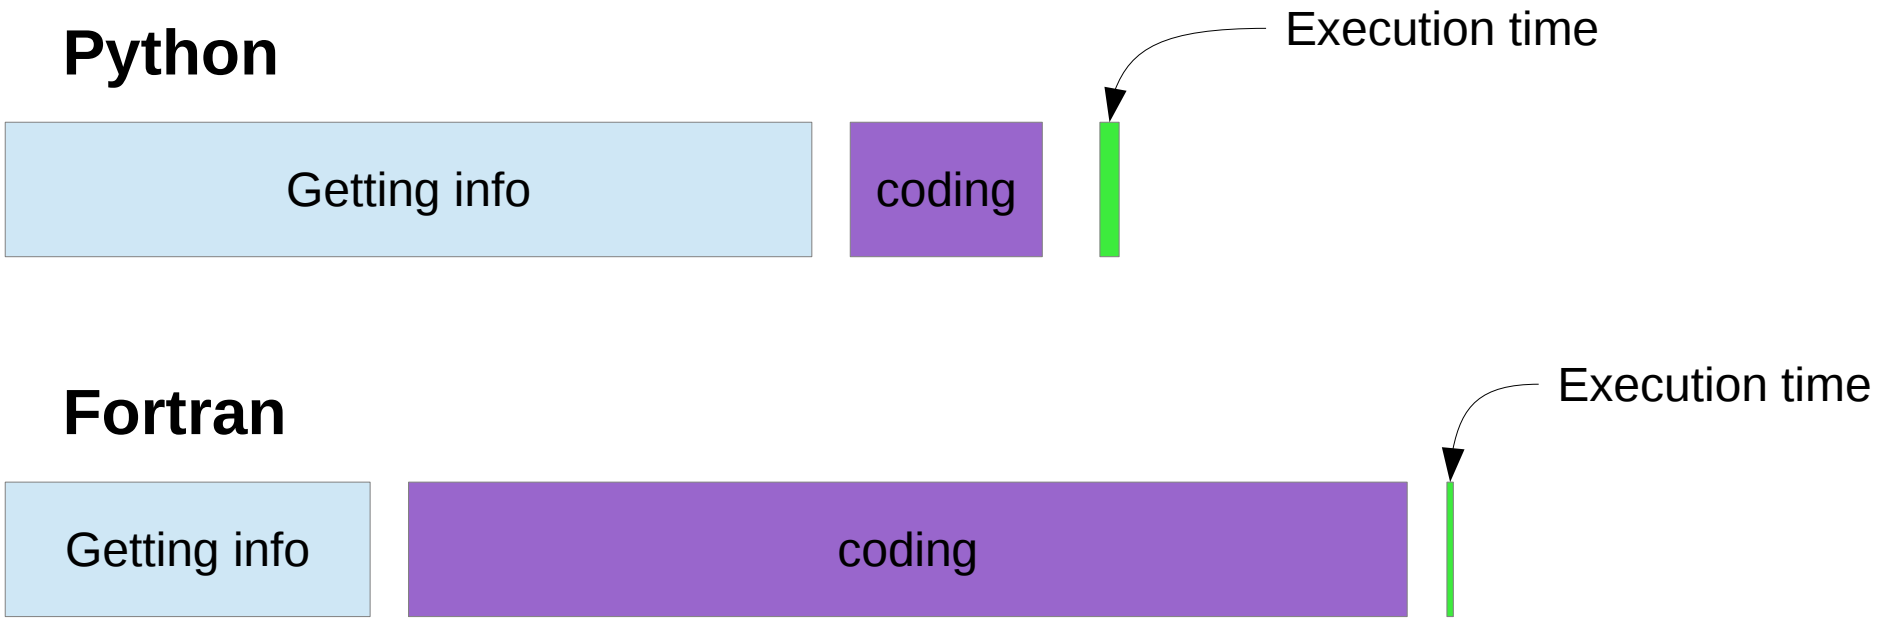
Low level vs. high level

- Python is a high level language
- You can focus on:
  - Low level issues
  - Higher complexity of problems

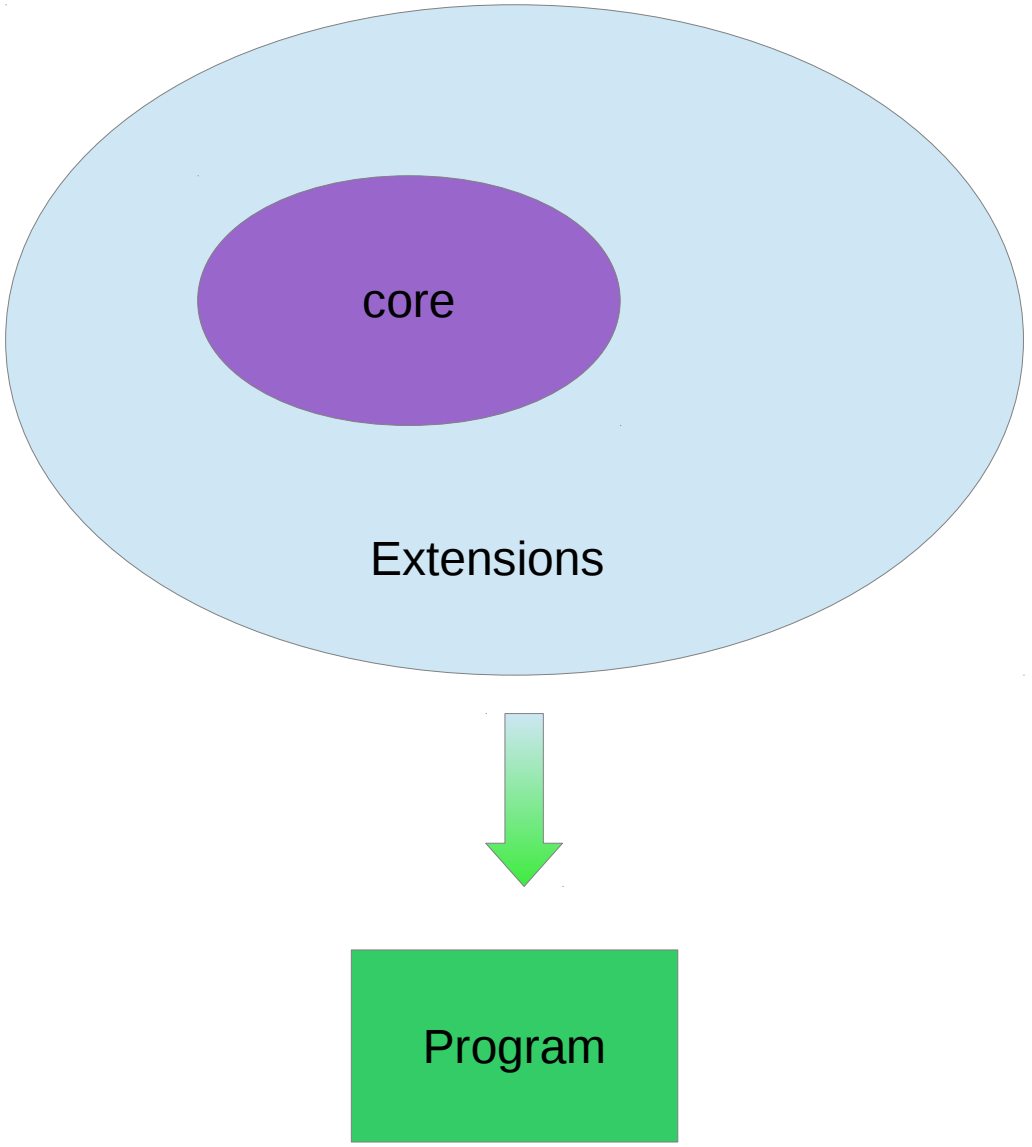
- Low level issues
  - Variable types
  - Machine precision
- But also
  - Extend
  - Mantain
  - Document code

Python vs. Fortran/C

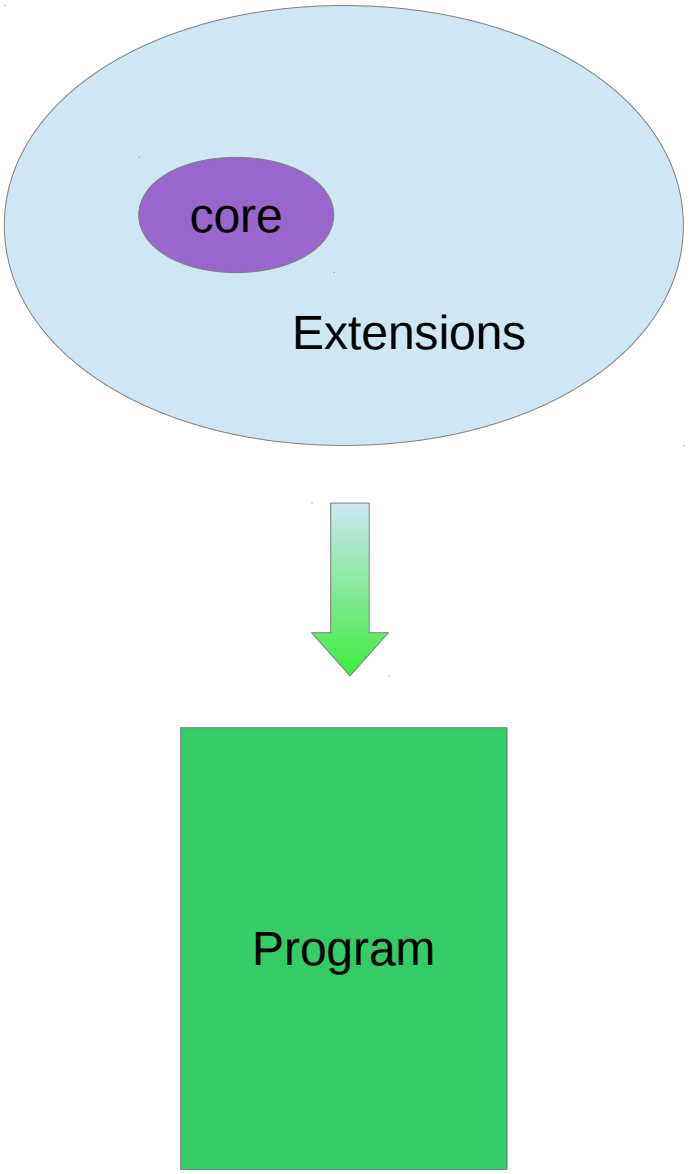
Different time distribution to get a task done



Python



Fortran/C



Python for science

- The homogenization of scientific computing, or why Python is steadily eating other languages' lunch
  http://www.talyarkoni.org/blog/2013/11/18/the-homogenization-of-scientific-computing-or-why-python-is-steadily-eating-other-languages-lunch/
- 10 Reasons Python Rocks for Research (And a Few Reasons it Doesn't)
  http://www.stat.washington.edu/~hoytak/blog/whypython.html

Hello World program

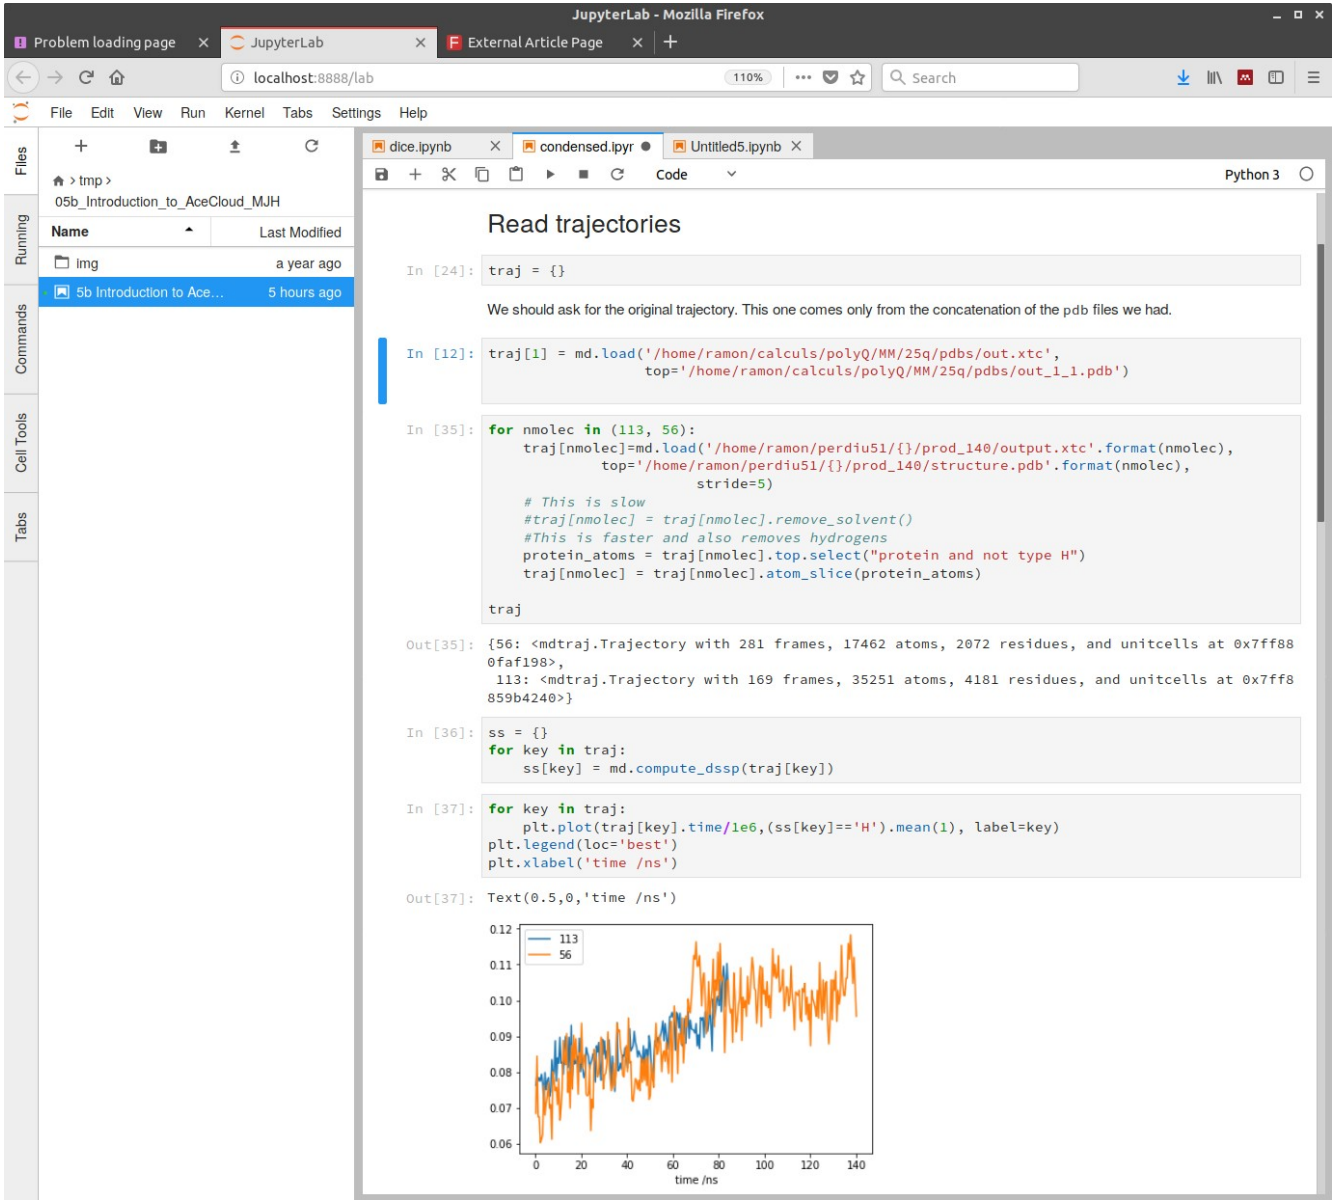
```
print(“Hello World!”)
```

```
print(“Hello World!”)
```

```
$ python3 hello.py
```

Interactive shells

- python
- IDLE
- **JupyterLab (previously called ipython)**
  - console
  - **notebook**
- spyder
- eric
- PIDA
- Sage



Python distributions

- Anaconda
  - https://www.continuum.io/downloads
- Enthought Canopy
  - https://www.enthought.com/products/canopy/

Dynamically typed

```
>>> a = 4
>>> type(a)
<class 'int'>
>>> b = 7.6
>>> type(b)
<class 'float'>
>>> type(a+b)
<class 'float'>
>>> c = 'Hola'
>>> c + ' Que tal?'
'Hola Que tal?'
>>> c + a
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: Can't convert 'int' object to str implicitly
```

Which python version?

- Language is fast evolving
- 2 versions now coexist: 3.x and 2.x
- These versions are not completely compatible
- 3.x is better and continued
- 2.x has some software still not ported
- Both can safely coexisit
  - Packages and shells are for a specific version
- `2to3 -w hello.py`

Language elements

Numbers

Integers:

```
> i = 5
> j = i**i**i
```

Limited by amount of memory:

```
>>> i.bit_length()
3
>>> j = i**i**i
>>> j.bit_length()
7257
>>> 9 % 5 #modulo
4
```

Floating point:

```
>>> x = 5.
>>> y = x**x**x
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
OverflowError: (34, 'Numerical result
   out of range')
```

Division vs integer division (Python 3):

```
>>> 3/2
1.5
>>> 3//2
1
>>> j/i #Returns a Float
```

Assignments

Explicit notation:

```
> i = i+1
> j = j / 10.
```

Short notation:

```
> i += 1
> j /= 10.
```

Floating point:

```
>>> x = 5.
>>> y = x**x**x
Traceback (most recent call
   last):
  File "<stdin>", line 1, in
   <module>
OverflowError: (34, 'Numerical
   result out of range')
```

strings

Strings:

```
> str(6.7)
> c ='Hola'
```

Operations:

```
> s='numeric ' +'python'
> len(s)
> s[5]
'i'
> s.split()
['numeric', 'python']
```

```
> print('Result: %5.3f' % (11./3.))
3.667
```

Non mutable:

```
> s[6]
> s[6]='7' #Error!
```

Regular expressions

```
import re
```

Lists, sets and tuples

- Fortran **`dimension`**:

  much more flexible

```
> l=[6, 'a', [5,[9,8,7,6]],
   -6.5, (True, True)]
> [1,2]+[3,4]
> l.append(6)
```

- sets:

```
s=set([4,3,2,3])
> 4 in s
True
> s
set([2, 3, 4])
```

- Tuples are unmutable lists

```
t=(1,2,3)
```

Lists, sets and tuples

List indexing and methods:

```
> l = list(range(10))
> l[4] = 20
> l[4:]
> l[-4]
> l[:]
> l[::-1] #reverse
> l.reverse()
> l.pop()
> l.extend([3,4,5])
> l.sort()
```

Set methods:

```
> s1=set([1,2,3,4])
> s2=set([3,4,5,6,7])
> s1.union(s2)
> s1.intersection(s2)
> s1.difference(s2)
> s2.difference(s1)
> s1.intersection(s2) == s2 & s1
True
> s1 - s2 == s2 - s1
False
```

Uses of lists, sets and tuples

- Calculate and keep all the primes < 1000
- Given a coordinate file, calculate for each atom a list of all the atoms that are at less than 0.2nm.
- Get the solutions of a quadratic equation (0,1,2) or (real vs. complex).
- http://docs.python.org/3/tutorial/datastructures.html

Copying and looping over lists

lists are treated as pointers:

copying lists, makes a copy of the pointer.

```
> l=[1,2,3,4]
> l2=l
> l[2]=1000
l1
[1, 2 , 1000, 4]
```

Looping over lists:

Fortran/C style:

```
num=[2,3,2,3,4,5,5]
for i in range(len(num)):
    print(num[i])
```

Pythonic style:

```
for item in num:
    print(item)
```

This can be used for sets, dictionaries, and tuples.

Dictionaries

Setting elements:

```
> phone={}
> phone['Ramon']='1242'
> phone['Joan']='1323'
> phone['Quique']='1242'
> phone.keys()
['Quique', 'Joan', 'Ramon']
> d2 = dict(Ramon=1242, Joan=1323,
  Quique=1242)
```

Dictionaries are not ordered

Getting elements:

```
> for key in phone:
...  print(key, phone[key])
Quique 1242
Joan 1323
Ramon 1242
```

Removing elements:

```
> del(phone['Ramon'])
```

The beauty of Python blocks

We are usually told to indent blocks for clarity.

Python makes this the syntax rule to identify blocks.

The code has to be nice!

Convention:

- Use 4 spaces
- Use spaces, not tabs.

```
while iter < maxIter:
    x = f(x)
    iter = iter + 1

if i>0:
    print("i is positive")
elif i==0:
    print("i is zero")
else:
    print("i is negative")
```

Execution control: if

if... elif... else

```
if <condition>:
  <block>
elif <condition>:
  <block>
else:
  <block>
```

```
4==4 #True
5!=4 #True
4>=5 #False
4 in [4,5] #True
result=True
if result: print('yes')
```

Execution control

Conditions can be combined with:

```
and or not ( )
```

Object identity:

```
> a=[1,2,3]
> b=a
> b is a
True
```

Any non-zero number or non-empty string is True:

```
> if []: print ('yes')
      else: print('no')
no
> if 5 and 'result':
    print('yes')
else:
    print('no')
yes
> if 5 or 1/0:  print('yes')
yes
```

for and while loops

For loops

```
> dict={4:'a',3:'b', 2:'c',
  1:'d'}
> for i in dict:
      print(i, dict[i])
```

While

```
while <condition>:
   <block>
```

Break continue pass

```
> pass # does nothing
```

`break`: Exit loop

```
if x>0:
  pass
else:
  break
```

`cycle`: Continue with the next iteration

list comprehension and enumerate

simple way to create lists:

```
> l=[x**2 for x in range(8)]
[0, 1, 4, 9, 16, 25, 36, 49]
```

with conditionals:

```
l2= [(i, -2*i+3) for i in l if i % 3 == 0]
[(0, 3), (9, -15), (36, -69)
```

Nested lists:

```
> [(x, y) for x in [1,2,3] for y in [3,1,4] if x != y]
[(1, 3), (1, 4), (2, 3), (2, 1), (2, 4), (3, 1), (3, 4)]
```

list comprehension and enumerate

Enumerate indexes lists:

```
line='how do you do?'
line=line.split()
for i, word in enumerate(line):
  print(i, word.upper())
0 HOW
1 DO
2 YOU
3 DO?
```

Enumerate returns an iterator

```
> enumerate(['a', 'b', 'c'])
<enumerate object at 0x1ebeaa50>
```

Be pythonic

Convert the negative elements of a list to positive

```
>>> x = [1, 2, -4, -5, 3, -5]
```

```
j = 0
while j < len(x):
    x[j] = abs(x[j])
    j += 1
```

```
for j in range(len(x)):
     x[i] = abs(x[i])
```

Or with list comprehensions

```
x = [abs(j) for j in x]
```

Or with functional programming

```
x= map(abs, x) #returns an iterator
```

http://docs.python-guide.org/en/latest/writing/style/

More python functions

```
print(3,4,5, sep='o', end='<<<<\n')
zip([1,2,3], ['a', 'b', 'c', 'd'])
a = input('Write a number: ')
len([1,2,3])
list(range(5))
range(20,10,-1)
sorted([5,4,3,5])
sum([5,4,3,5])
```

http://docs.python.org/3.3/library/functions.html

Mutable and immutable

- Mutable objects can be mutated.
  - Their identity remains the same
- Immutable objects are “mutated” by creating a new object

```
>>> a = 4
>>> id(a)
9157088
>>> a += 2
>>> id(a)
9157152
>>> s = 'Hola'
>>> id(s)
140165884365656
>>> s = s+ ' que tal?'
>>> id(s)
140165884365712
>>> ll = [3,4,5]
>>> id(ll)
140165884674416
>>> ll.append(6)
>>> id(ll)
140165884674416
```

Identity and equality

```
>>> 1.0 is 1.0
True
>>> 1.0 == 1.0
True
>>> 1 == 1.0
True
>>> 1 is 1.0
False
```

```
>>> a = 4
>>> b = a
>>> a is b
True
>>> id(a)
9157088
>>> id(b)
9157088
>>> l1 = [1,2,3,]
>>> l2 = l1
>>> l2 = l1[:]
>>> l2 is l1
False
>>> l2 == l1
True
```

Objects: everything

```
>>> a = 5
>>> isinstance(a, int)
True
>>> object
<class 'object'>
>>> int
<class 'int'>
>>> isinstance(a, object)
True
>>> issubclass(int, object)
True
```

Objects have variables:

```
> c = 4+5j
> c.real
```

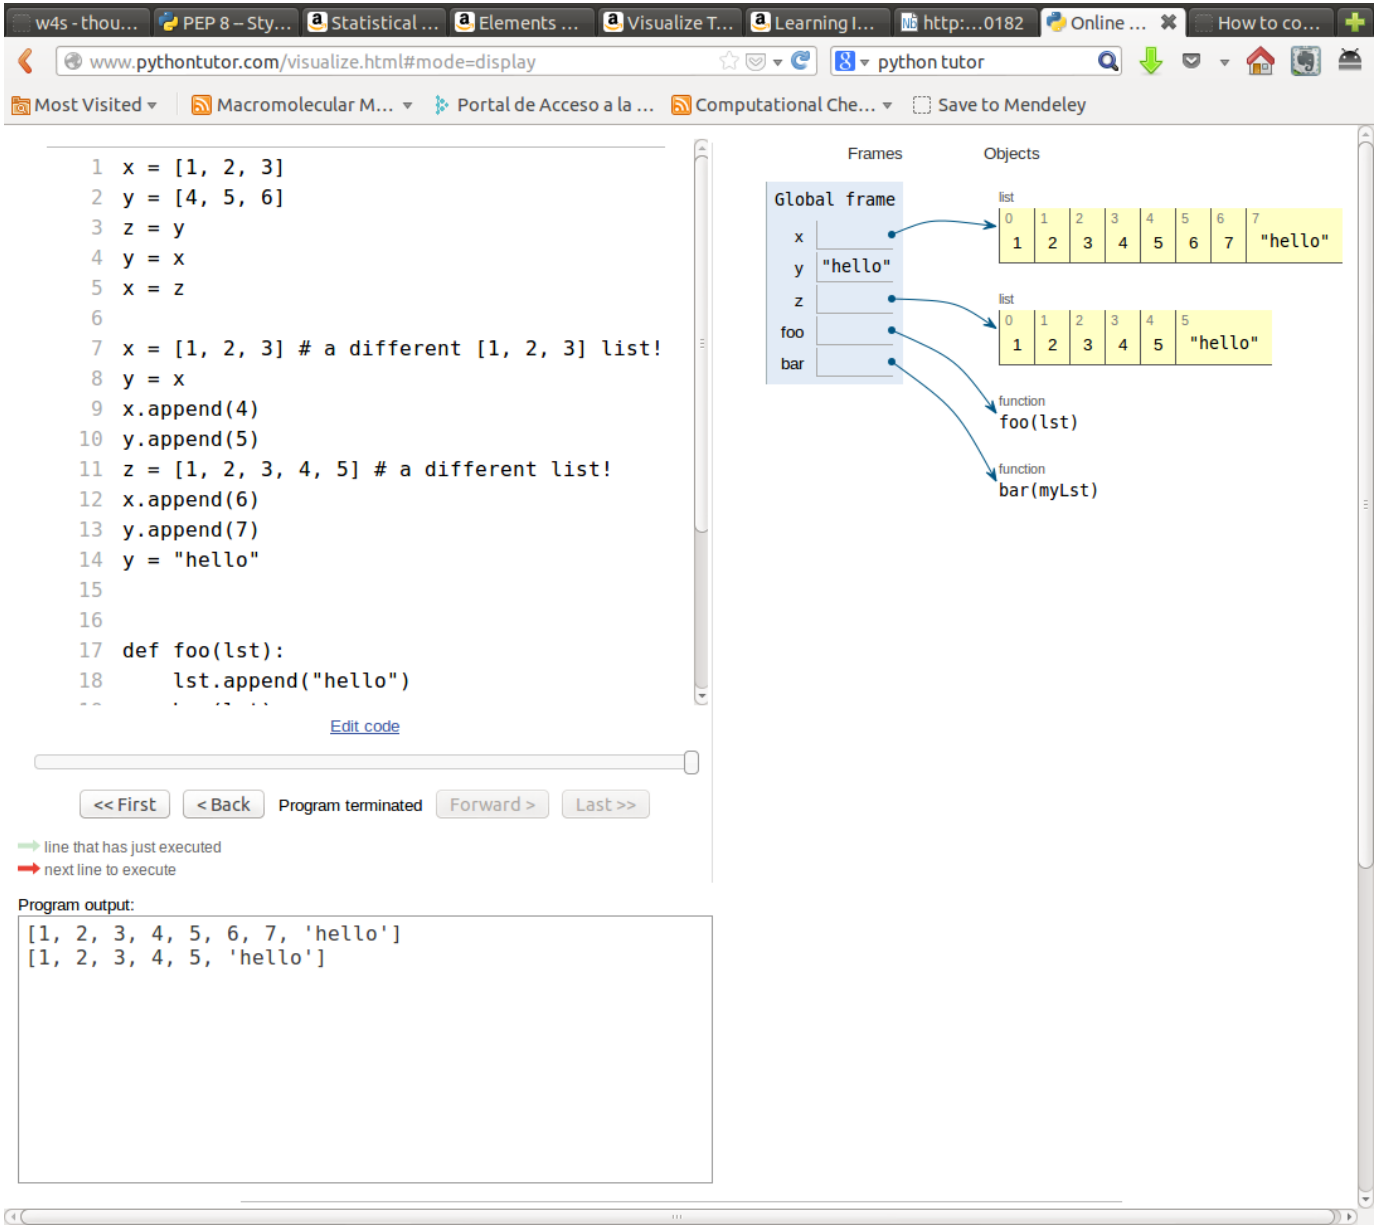
Objects have methods:

```
> c.conjugate #the method
> c.conjugate() #its call
```

And we can apply functions to objects:

```
> abs(c)
```

Python flow with pythontutor



try... except

“Look before you leap”:

```
def safe_divide_1(x, y):
  if y==0:
    print("Divide-by-0 attempt
   detected")
    return None
  else:
    return x/y
```

“It's easier to ask forgiveness than permission”:

```
def safe_divide_2(x, y):
  try:
    return x/y
  except ZeroDivisionError:
   print("Divide-by-0 attempt
   detected")
    return None
```

Short ipython tutorial

beyond python

TAB autocomplete:

- functions
- methods
- files
- …

`reload` command

cursor keys get history (for console only):

- even previous sessions!
- text + keys: previous match

?: intro to ipython

`%quickref`

`Ctrl-r` : previous commands

Without ipython:

`python3 -u script.py` enters interactive mode

Magic functions

```
%timeit x=10     : time the 'x=10' statement with high precision.
%%timeit x=2**100
x*100            : time 'x*100' with a setup of 'x=2**100'; setup code is not
                   counted.  This is an example of a cell magic.
%cpaste, %paste: Paste & execute a pre-formatted code block from clipboard.
%history
%load_ext
%run
%pdb: Control the automatic calling of the pdb interactive debugger.
%pylab
%timeit
%pwd
%cd
%%bash
```

http://ipython.org/ipython-doc/dev/interactive/tutorial.html

running scripts

`%run script.py`

`import script.py`

are not the same!

`%run script.py` is like `python3 script.py`

Imports are only “impoted” once in a session (see later %autoreload magic function)

ipython notebook

- Nice presentation
- Allows parallel execution
- Combines text and code
- Executable or exportable to:
  - html
  - LaTeX
  - python
- Start with: `ipython3 notebook`
- Examples:
  https://github.com/jrjohansson/scientific-python-lectures

Files

Files

- Files can be *text* or *binary*
- Files can be opened for read, write or append
  - `'r', 'w', 'a+'`
- `with open('name') as filein:`
  - Allows automatic file closure
  - Explanation of the `with` statement: http://effbot.org/zone/python-with-statement.htm

Reading / Writing Files

```
file_in=open('indata.txt','r')
file_out=open('outdata.txt','w')
for line in file_in:
    # Take some information (split() method is very useful!)
    x = float(line.split()[0])
    # Apply a given function (fact)
    fx = fact(x)
    # Write the result in an output file with a defined format
    file_out.write('{:010.3f}\n'.format(fx))
```

But for loading numerical data **Numpy** is more efficient. And **pandas** even more.

File parsing

- The basic:

```
for line in filein:
    do something
```

- Common things:

```
if 'optimized' in line:
    do something
line = line.split()
if line.upper().startswith('GEOM'): …
energy = float(line[2])
```

skipping lines

- Lines can be skipped by calling `next()` to a file:

```
for line in filein:
    if 'Optimized' in line:
        next(filein); next(filein) #skip two lines
        do something...
```

Formatting

- There are several function:

```
'12'.rjust(5), '12'.zfill(5)
```

- But `format` is more general:

```
print('{0:2d} {1:3d}'.format(x, x*x))
print("{:10.3f} {:10.3f} {:10.3f}".format(x,y,z))
```

- List of unkown length (use argument unpacking):

```
vals = np.linspace(0,1,11)
print((len(vals)*"{:10.2e} ").format(*vals))
```

http://docs.python.org/3/library/string.html#formatspec

Useful modules

- Similar to `ls`:

```
import glob
files = glob.glob(pattern)
```

- Working with shell-like commands:

```
import os
os.rename(src, dst)
os.mkdir(path)
os.chown(path, uid, gid)
os.getenv(key)
os.walk(directory)
```

http://docs.python.org/3/library/os.html

Useful modules

- Reading Excel files http://www.python-excel.org/:

```
import xlrd
```

  - Pandas uses this library
- Working with image files
  - http://scikit-image.org/
  - http://pillow.readthedocs.io/en/latest/

Numpy

Why Numpy / Scipy?

- Python (alone) is not efficient for numerical calculations
- Python (alone) is not practical for array manipulation
- Numpy provides the data types and methods for arrays
- Scipy provides more elaborate numerical methods
  - Optimization
  - Fast Fourier Transform
  - Linear algebra, etc

```
import numpy as np
import scipy.optimization
import scipy.stats as stats
```

numpy arrays

- without numpy:

```
> a=[[1,2],[3,4]]

> b=[[10,20], [30,40]]

> a+b

[[1, 2], [3, 4], [10, 20], [30, 40]]
```

- with numpy:

```
> a=np.array(a)

> b=np.array(b)

> a+b

array([[11, 22],[33, 44]])
```

- Array creation

```
a=np.array([1,2,3,4]).reshape([2,2])

a=np.array([[1,2], [3,4]])

a=np.zeros([2,2], dtype=int)

a[0,0]=1.

a=np.ones((4,4))

a=np.arange(10)

a=np.diag([1,2,3,4])

a=np.tile(a, (10,2))

a=np.identity(3)

a=np.linspace(-5,5, 20)
```

Ufuncs

- Unary:

```
a.min()
a.sum()
a.cumsum()
a.mean()
np.argmin(a)
np.exp(-a)
np.cov(a)
a.tolist()
```

- Binary:

```
a + b
np.dot(a, b)
```

- Applying to parts of an array:

```
> a=np.array([[1,2], [3,4]])
> a.min(axis=0)
array([1, 2])
a.sum(axis=1)
array([3, 7])
```

- Python functions are less efficient than numpy functions:

`a.sum()` better than `sum(a)`

`np.min(a)` better than `min(a)`

many implemented as methods and functions

Accessing array elements

- Slicing:

```
> a[2:5]

> b[:, ::5]

> a[1:4, ...]
```

- Fancy indexing:
  - Boolean arrays (masks):

```
> a = np.arange(10,15)
> indices = (a**2 > 115) & (a < 14)
> a[indices]
array([11, 12, 13])
```

  - With lists:

```
> a = np.arange(10,15)
> y=a[[4,4,1]]
> y
array([14, 14, 11])
> a[[4,4,1]] = [-2, -4, 5]
> a
array([10,  5, 12, 13, -4])
```

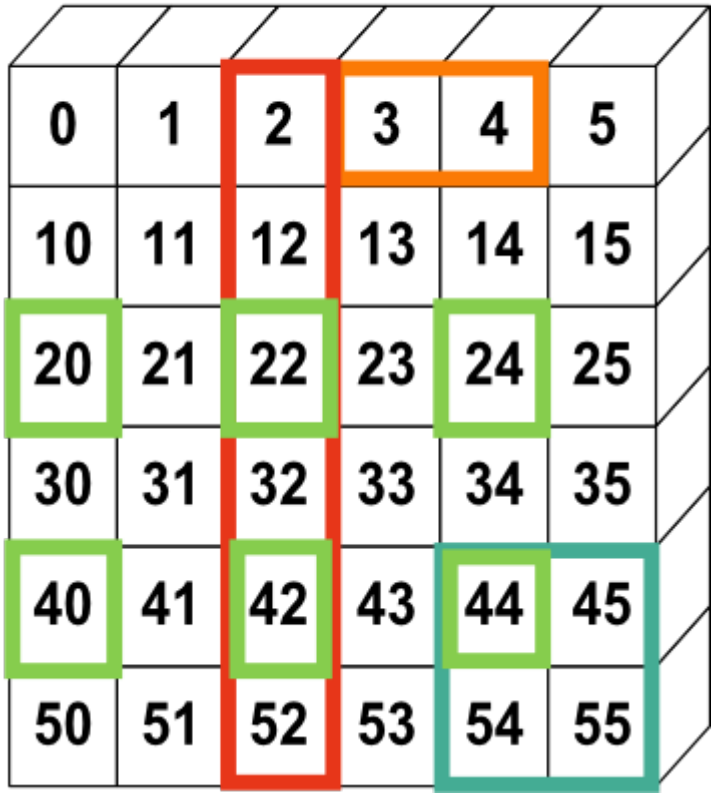
Accessing array elements

```
>>> a[0,3:5]
array([3,4])

>>> a[4:,4:]
array([[44, 45],
       [54, 55]])

>>> a[:,2]
array([2,12,22,32,42,52])

>>> a[2::2,::2]
array([[20,22,24]
       [40,42,44]])
```



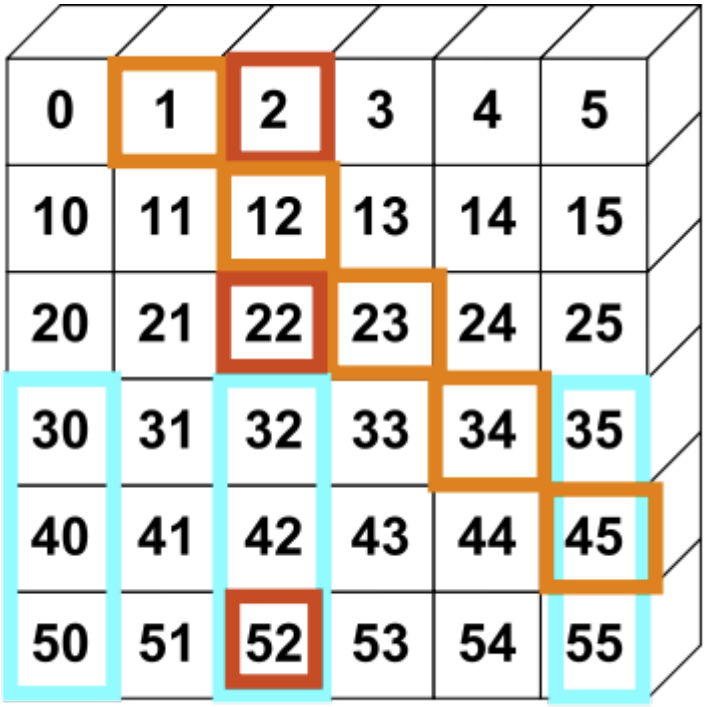
From: https://scipy-lectures.github.io/intro/numpy/array_object.html

Accessing array elements

```
>>> a[(0,1,2,3,4),(1,2,3,4,5)]
array([ 1, 12, 23, 34, 45])

>>> a[3:,[0, 2, 5]]
array([[30, 32, 35],
       [40, 42, 45]])
       [50, 52, 55]])

>>> mask = array([1,0,1,0,0,1],
                 dtype=bool)
>>> a[mask,2]
array([2,22,52])
```



From: https://scipy-lectures.github.io/intro/numpy/array_object.html

Accessing array elements

- Slices return views

```
> a = np.arange(5)
> y=a[2:5]
> y *= -1
> a
array([ 0,  1, -2, -3, -4])
> y.flags.owndata
False
```

- np.where

```
> np.where((a>=2)&(a<4), a**2, -1)

Array([-1, -1,  4,  9, -1])
```

- np.choose
  - Powerful, but complex!
- np.nonzero

- Boolean arrays return copies

```
> a = np.arange(5)
> y = a[a>1]
> y *= -1
> a
array([0, 1, 2, 3, 4])
> y.flags.owndata
True
```

- Fancy indexing returns copies:

```
> a = np.arange(5)
> y=a[[2,3,4]]
> y *= -1
> a
array([0, 1, 2, 3, 4])
> y.flags.owndata
True
```

Broadcasting

```
> a = 4.
> b = np.array([1,2,3])
> c = np.array([[1,2,3], [4,5,6]])
> b+a, c+a
(array([ 5.,  6.,  7.]), array([[  5.,   6.,   7.],
        [  8.,   9.,  10.]]))
> b+c
array([[2, 4, 6],
       [5, 7, 9]])
> c.dot(b)
> b.dot(c)
ValueError: objects are not aligned
> b[1:]*c
ValueError: operands could not be broadcast together with shapes (2) (2,3)
> b[1:]*c.T
```

- Use `matrix` if you want more algebra-like behaviour

Broadcasting

- Change the shape to allow for broadcasting:

```
> c = np.array([[1,2,3], [4,5,6]])
> b = c.mean(axis=1)
> c+b[:,np.newaxis] #or c+b[:,None]
> c+b.reshape((-1,1))
```

- Or keep the shape:

```
> b = c.mean(axis=1, keepdims=True)
> c+b
```

- See also:
  - `np.atleast_2d`, `np.atleast_1d` and `np.atleast_3d`

np.einsum

- Complex but powerful function to avoid the use of loops
  - Dot product, outer product, and others can be written as `einsum`

```
> c = np.array([[1,2,3], [4,5,6]])
> np.allclose(c.dot(c.T), np.einsum('ij, kj->ik',c,c))
True
```

- See numpy documentation and the following blog entry:
  - http://docs.scipy.org/doc/numpy-1.10.0/reference/generated/numpy.einsum.html
  - http://ajcr.net/Basic-guide-to-einsum/

array functions and methods

- Array reduction and logical operations:

```
> a=np.arange(5)
> np.all(a>3)
False
> np.any(a>3)
True
> a > 3
array([False, False, False, False,
 True], dtype=bool)
> (a > 3) & (a < 5)
array([False, False, False, False,
 True], dtype=bool)
```

- Some details of memory use:
- `> a.flags`

```
 C_CONTIGUOUS : True
 F_CONTIGUOUS : True
 OWNDATA : True
 WRITEABLE : True
 ALIGNED : True
 UPDATEIFCOPY : False
```

Loading and saving data

- Pickle is the usual way to save and restore data in Python
- We often have data file in text format:

```
#Dist Energy
1.0 34.
1.2 38.
2.4 42.
```

- `> f=np.loadtxt(“energies.dat”)`

```
> f
array([[  1. ,  34. ],
       [  1.2,  38. ],
       [  2.4,  42. ]])
```

- Save single arrays with:

```
> np.save('result_y', y)
```

- Save in text mode with:

```
> np.savetxt('result_y', y)
```

- and multiple arrays with (saves a dictionary):

```
> np.savez('results', x, y)
```

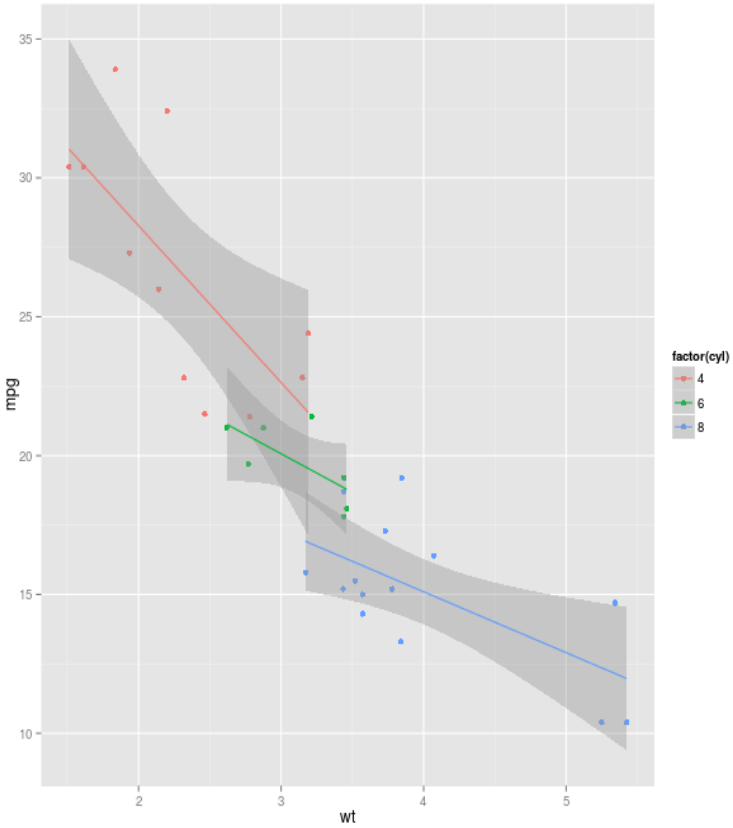
- Recover them with load:

```
> y=np.load('results_y.npy')
```

```
> npz=np.load('results.npz')
```

Acess R from python

- Use the rpy2 module.
- From the documentation:



```
import math, datetime
import rpy2.robjects.lib.ggplot2 as ggplot2
import rpy2.robjects as ro
from rpy2.robjects.packages import importr
base = importr('base')
datasets = importr('datasets')

mtcars = datasets.data.fetch('mtcars')['mtcars']
pp = ggplot2.ggplot(mtcars) + \
     ggplot2.aes_string(x='wt', y='mpg', col='factor(cyl)') + \
     ggplot2.geom_point() + \
     ggplot2.geom_smooth(ggplot2.aes_string(group = 'cyl'),
                         method = 'lm')
pp.plot()
```

Other tutorials

- Take a look at these tutorials:
  - http://wiki.scipy.org/Tentative_NumPy_Tutorial
  - From: http://jrjohansson.github.io/
    - Lecture-2-Numpy.ipynb
    - Lecture-3-Scipy.ipynb

matplotlib

Matplotlib

- A module for plotting 2D and 3D data
- Combines well with numpy
- Starts with

```
import matplotlib.pyplot as plt
%matplotlib inline
```

`import pylab` or similar is deprecated.

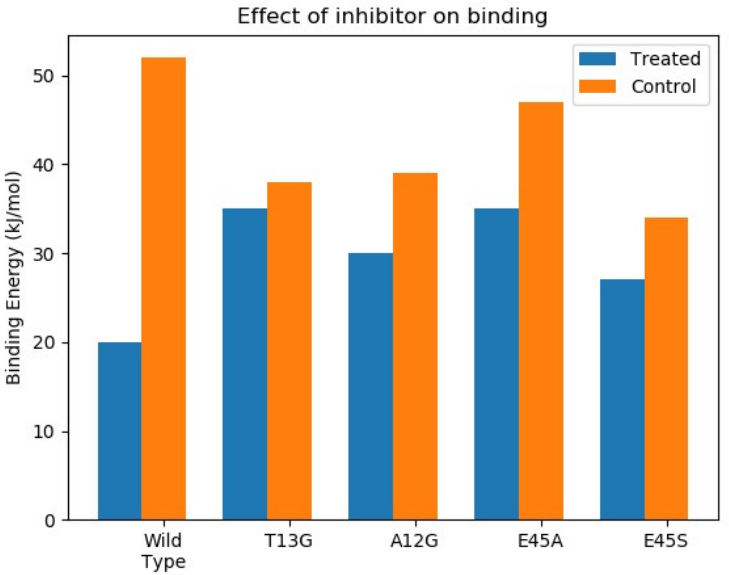
Matplotlib

Simplest plots:

```
> plt.plot([1,2,3], [1,4,9])
> plt.plot(x, sin(x), '--') #where x is a numpy array
> plt.figure() # creates new figure
> plt.clf() # Clears current figure
> plt.matshow(m) # m is a 2D array
> plt.imshow(m) # m is a 2D array. Similar to matshow.
> d = np.loadtxt('data.txt')
> plt.plot(d[:,0], d[:,1], 's') #just slightly longer than
gnuplot
```

Matplotlib

Totally reproducible figures



```
N = 5
treated = (20, 35, 30, 35, 27)
control = (52, 38, 39, 47, 34)
ind = np.arange(N)  # the x locations for the groups
width = 0.35       # the width of the bars

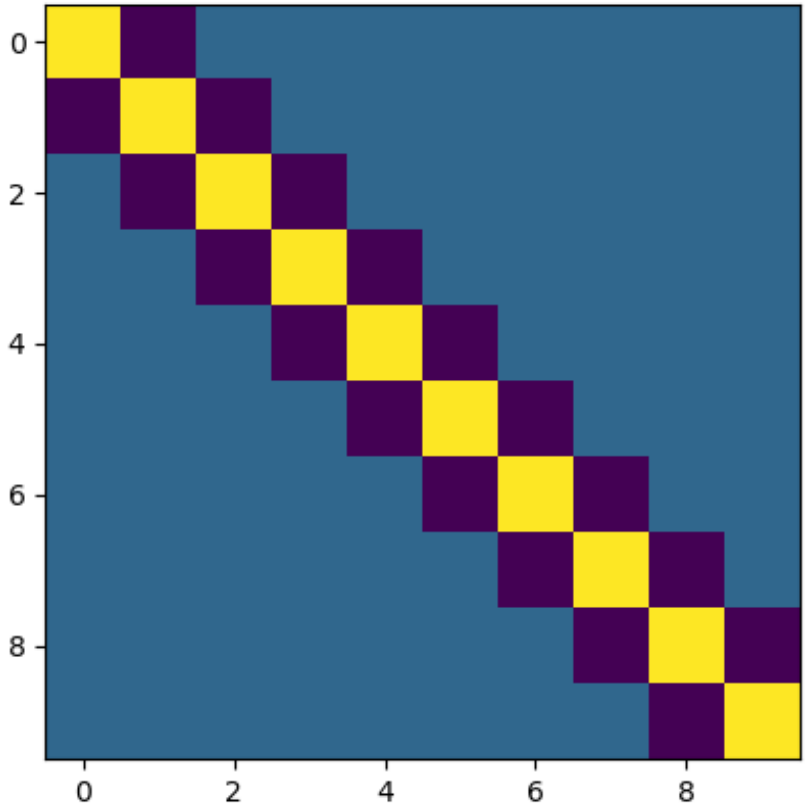
fig, ax = plt.subplots()
rects1 = ax.bar(ind, treated, width, label='Treated')
rects2 = ax.bar(ind+width, control, width, label = 'Control')

# add some
ax.set_ylabel('Binding Energy (kJ/mol)')
ax.set_title('Effect of inhibitor on binding')
ax.set_xticks(ind+width)
ax.set_xticklabels( ('Wild\nType', 'T13G', 'A12G', 'E45A', 'E45S') )
ax.legend()
```

Plotting matrices

```
m=np.diag(2*np.ones(10))+np.diag(-1*np.ones(9),1)+np.diag(-1*np.ones(9), -1)

plt.imshow(m)              # plt.matshow(m) is very similar
```

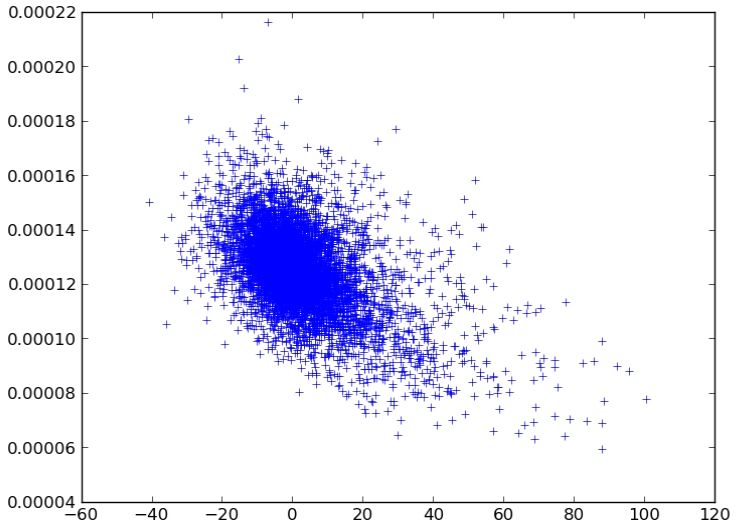


Matplotlib styles

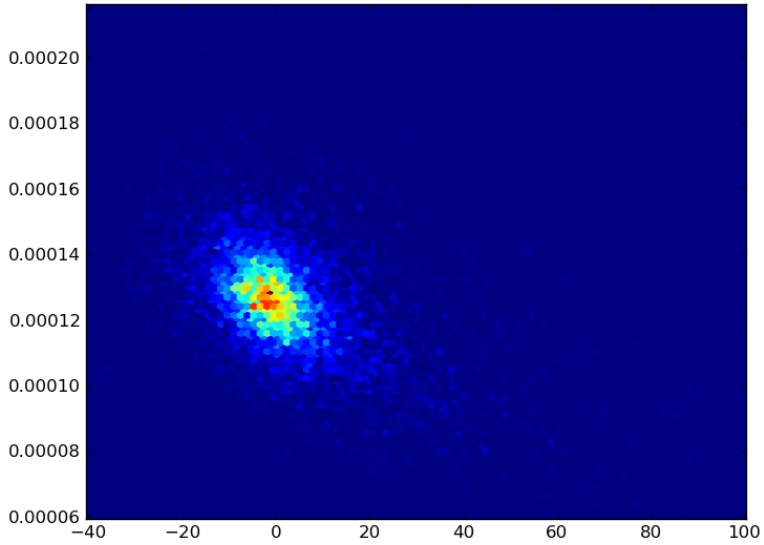
- Since version 1.5 several default styles.
- Try the following code

```
x= np.linspace(0, np.pi, 100)
for s in plt.style.available:
    with plt.style.context(s):
        plt.figure()
        plt.title(s)
        plt.plot(x,np.sin(x)*np.cos(x**2), label='A')
        plt.plot(x,np.sin(x)*np.cos(x**2)*np.cos(x), label='B')
        plt.plot(x,np.sin(x)-np.cos(x)*np.sin(x), label='C')
        plt.legend(loc='best')
```

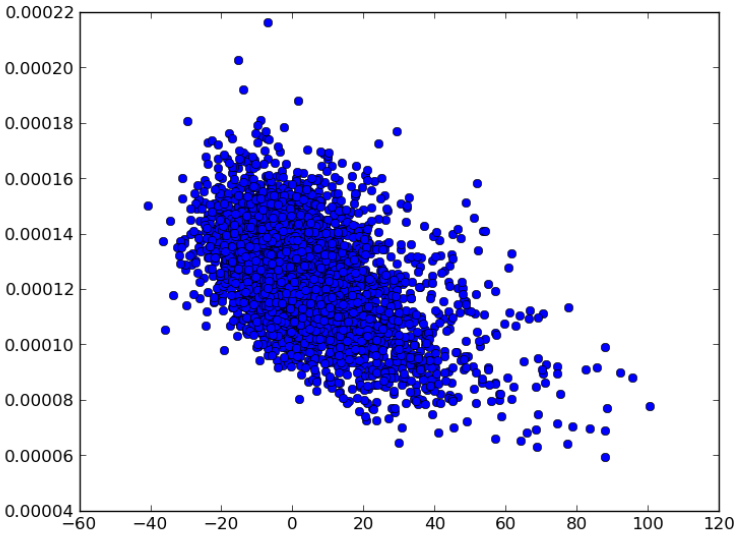
Plotting lots of points:hexbin



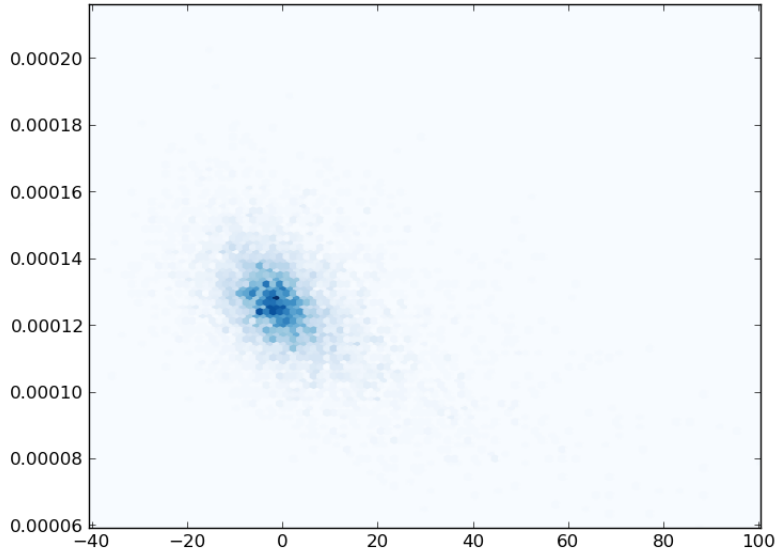
```
plt.plot(x, y, '+')
```



```
plt.hexbin(x, y)
```

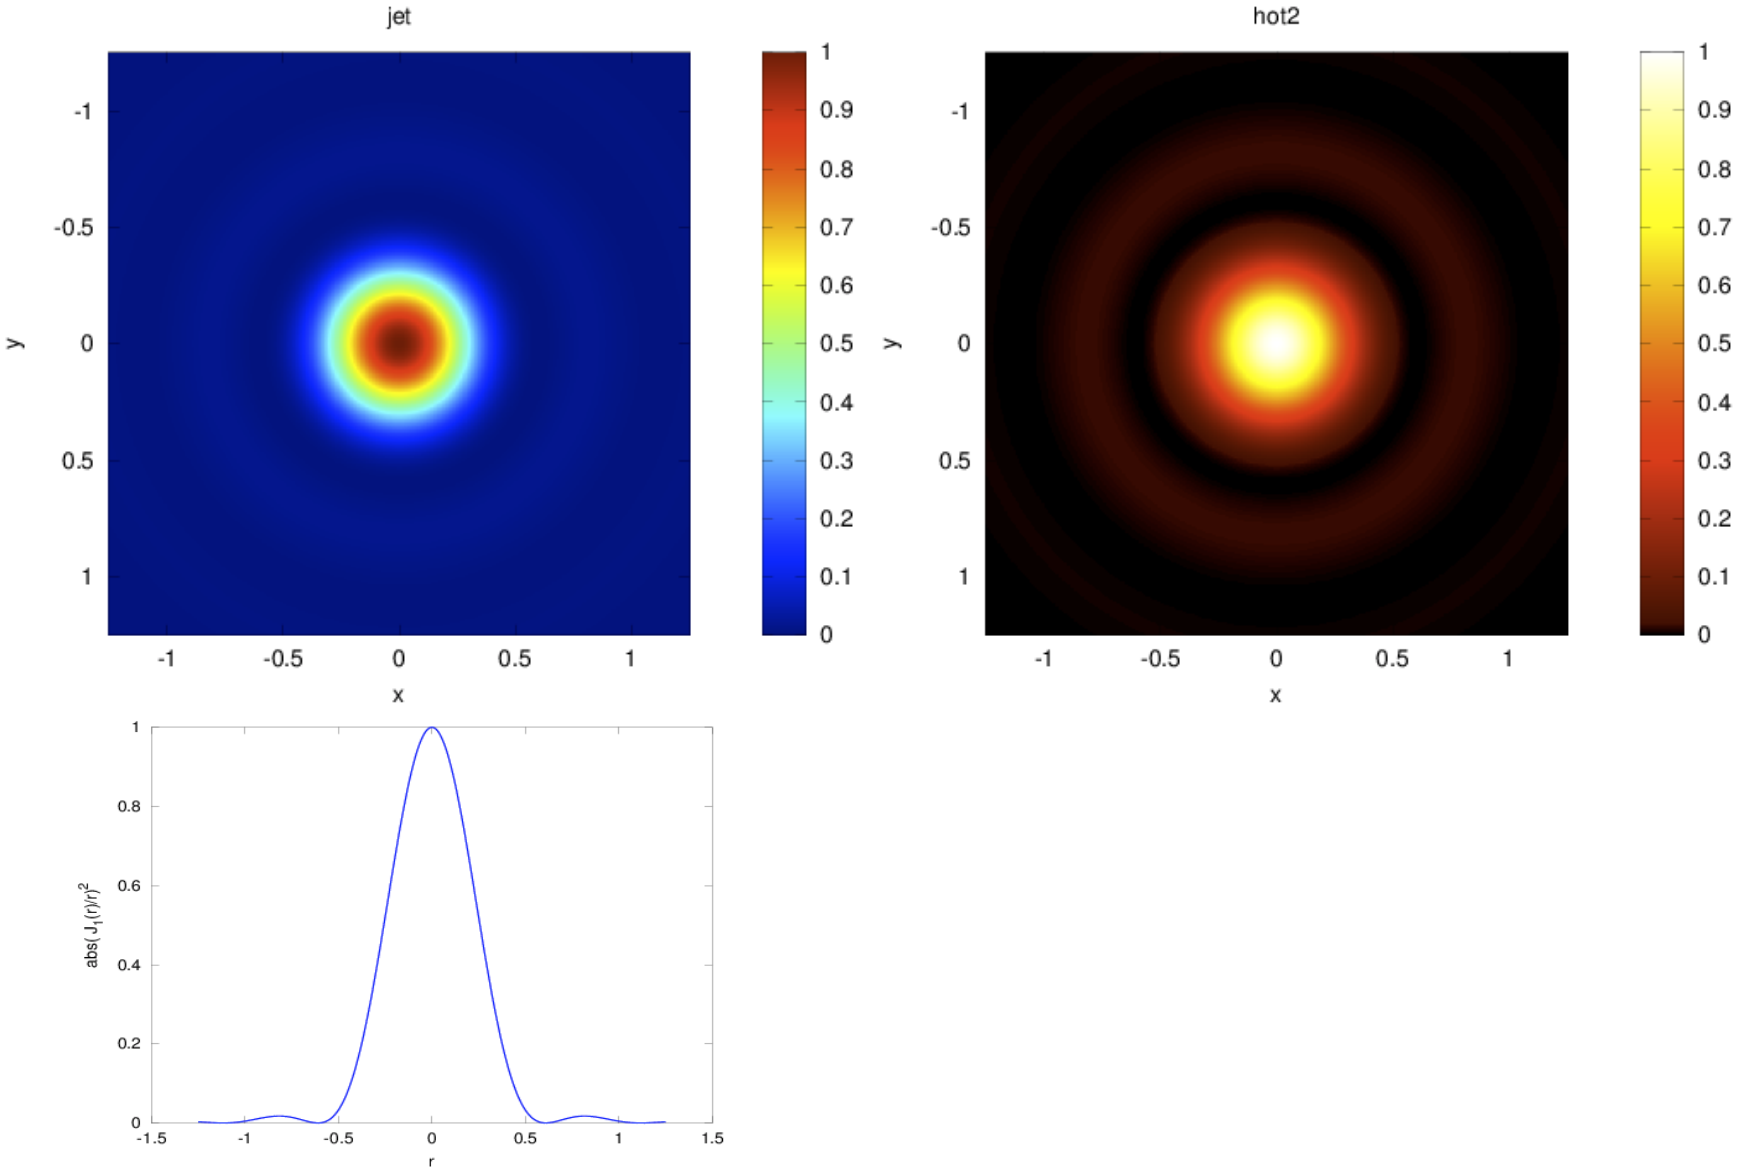


```
plt.plot(x, y, 'o')
```



```
plt.hexbin(x, y, cmap=pylab.cm.Blues)
```

Jet is not a good colormap



http://cresspahl.blogspot.com.es/2012/03/expanded-control-of-octaves-colormap.html
https://jakevdp.github.io/blog/2014/10/16/how-bad-is-your-colormap/

Matplotlib

- Do Lecture-4-Matplotlib.ipynb from http://jrjohansson.github.io/
  - Other interesting material there...
- Check matplotlib gallery
  - http://matplotlib.org/gallery.html
- Quick reference of symbols and colours:
  - http://www.loria.fr/~rougier/teaching/matplotlib/#quick-references

    (part of a larger tutorial)
- Some more tricks and examples:
  - http://wiki.scipy.org/Cookbook/Matplotlib

Extensions

- Seaborn
  - Data visualization
  - Nice color palettes from http://colorbrewer2.org/
  - https://stanford.edu/~mwaskom/software/seaborn/
- Bokeh:
  - http://bokeh.pydata.org/en/latest/
- Plotly:
  - https://plot.ly/
- http://pbpython.com/visualization-tools-1.html

Pandas

Pandas

- library providing high-performance, easy-to-use **data structures** and data analysis tools for Python
- Follow this notebook
  - As an example of what can be found out there...
- Watch the video:
  - https://www.youtube.com/watch?v=0CFFTJUZ2dc
- Download the notebook and the data:
  - https://github.com/jonathanrocher/pandas_tutorial

Functions and modules

Functions

defined by def and a colon:

```
def add(x,y):
    return x+y
```

Remember indentation!

Automatic (and recommended) documentation:

```
def add(x,y):
    """ Returns the
      sum of 2 numbers"""
    return x+y
```

Functions can be seen as both fortran procedures and functions but...

Arguments are passed by reference

there is access to global variables:

```
> def x_val(): print(x)
> x=60
> x_val()
60
```

Functions II

Function variables are local :

```
> def x_val():
...   x=40
...   print(x)
> x=60
> x_val()
40
> x
60
```

to assign variables, use `return`

```
def x_val():
...   x=40
...   print(x)
...   return x
> x = xval()
40
> x
40
```

Functions III

Mutable objects are passed by reference:

```
> def square_0(lst):
...  lst[0]*=lst[0]
> a=[3,2,1]
> square_0(a)
> a
[9,2,1]
```

Copy variables that need to be preserved:

```
> a_copy=a[:]
> square_0(a)
> import copy
> import copy
> a_copy=copy.deepcopy(a)
```

Functions IV

Functions can have default arguments :

```
> def submit(job, priority=10,
   nprocs=1):
...  pass
> submit('job1.sh')
```

Function arguments do not have explicit types.

```
> add('Python ', 'summerschool')
Python summerschool
```

Functions can be recursive

```
def fact(n):
  if n == 1:
      return 1
  else:
      return n * fact(n-1)
```

Argument unpacking

Starred arguments are tuples that collect positional arguments :

```
> def prod(*args): ...
> prod(2,3,4)
> x = (4, 5, 6)
> prod(*x)
```

In `prod, args=(2,3,4)`

Keword arguments can be passed as a dictionary:

```
> options = dict(paper='A4', color = True)
print_setup(options)
```

Unpacking can be a convenient way to print a list:

```
> vals = [1,2,3,4,5]
> print((4*'{:03d} ').format(*vals))
001 002 003 004
```

https://docs.python.org/3/tutorial/controlflow.html#unpacking-argument-lists

Lists or iterators?

- Lists are iterable objects
- Iterators generate objects on-the-fly
- Iterators can be created with a generator function
  - Uses `yield` satement
- Relevant for efficiency

```
def rang_llista(n):
    result = []
    i = 0
    while i<n:
        result.append(i)
         i += 1
    return result
```

```
def rang_gen(n):
    i = 0
    while i<n:
        yield i
        i += 1
```

Modules

- Modules allow packing libraries or extensions
- There are built-in and external modules
- When imported modules are executed
- Modules can be written in C or Fortran!

```
> import math
> m = math
> import math as m
> from math import cos, sin
> from math import * #dangerous. All into the same namespace
```

Modules

- Python checks if a module is already loaded.
  - The interpreter does not reload a module already imported
  - This can cause unexpected behaviour interactively
- Ipython has a more versatile module loading

```
%load_ext autoreload

autoreload 2 #Will reload a module if it changes
```

Some useful modules

- sys — System-specific parameters and functions
- os — Miscellaneous operating system interfaces
- os.path — Common pathname manipulations
- glob — Unix style pathname pattern expansion
- re — regular expressions
- copy — Shallow and deep copy operations
- argparse — Parser for command-line options, arguments and sub-commands
- subprocess — Subprocess management
- inspect — Inspect live objects

Some useful modules

```
if len(sys.argv!=3):
    print('Error: Use two arguments.')
    sys.exit()

method = sys.argv[1]
filelist = glob.glob('/home/ramon/*')
for fileName in filelist:
    if os.path.isfile(fileName): print(fileName)
```

Modules: too many…

From the python documentation:

It is also possible to use a list as a queue, where the first element added is the first element retrieved (“first-in, first-out”); however, lists are not efficient for this purpose. While appends and pops from the end of list are fast, doing inserts or pops from the beginning of a list is slow (because all of the other elements have to be shifted by one).

To implement a queue, use `collections.deque` which was designed to have fast appends and pops from both ends.

Modules: too many...

```
>>> import math
>>> import cmath
>>> import numpy.lib.scimath as scimath
>>> math.sqrt(4)
2.0
>>> math.sqrt(-4)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: math domain error
>>> cmath.sqrt(4)
(2+0j)
>>> cmath.sqrt(-4)
2j
>>> scimath.sqrt(4)
2.0
>>> scimath.sqrt(-4)
2j
```

Working with your modules

- Import reads from local directory and from the directories in `sys.path` (`import sys` first)
- Put your modules in a directory and add it to the environtment variable `$PYTHONPATH`.
- Python will add the directories in `$PYTHONPATH` to `sys.path`
- Document your modules and the functions therein.
- Use `if __name__=='__main__':` to execute code only if Python is running the module, and not if it is imported.
  - http://stackoverflow.com/questions/419163/what-does-if-name-main-do

Installing external Modules

- Use conda distribution. Then `$ conda install module`
- Many come as part of the linux distributions (usually older versions that those in conda or PyPI)
  - ipython, numpy, biopython...
- For modules in the PyPI repository(most of them) https://pypi.python.org/pypi
  - `(sudo) pip3 install module`
- Manual installation (dependencies have to be also manually installed):

```
$ python setup.py build
$ (sudo) python setup.py install
```

Updating external Modules

- With conda `$ conda update module`
- For modules in the PyPI repository(most of them)
  https://pypi.python.org/pypi
  - `pip3 install -U module`
- `pip` can also be used in the conda installation.
- Remeber that modules are installed for a given version of python.
  If you have python 2.x and 3.x you need to check for which version you are installing. For example using `pip3` or

```
$ which pip
```

Scipy

Linear algebra

- Support for LAPACK, BLAS and ATLAS
  - Can make Scipy compilation more involved

```
> A=matrix(random.rand(5,5))
> A.I
> linalg.det(A)
> linalg.eigvals(A)
> linalg.eig(A)
> linalg.svd(A)
> linalg.cholesky(A)
```

- Solving linear systems:
  - **A.x=b**

```
> b=matrix(random.rand(5)).reshape((5,1))
> linalg.solve(A,b)
```

- LAPACK, BLAS wrappers

```
> from scipy.lib import lapack
> from scipy.lib import blas
blas.fblas.sdot?
```

Optimization

- There are different optimization methods:

```
> import scipy.optimize as so
```

- Some only need the function value:

```
> fmin, fmin_powell
```

- Some need the gradient or the hessian:

```
> fmin_cg, fmin_bfgs, fmin_ncg
```

- Some look for global minima:

```
> anneal
```

- Remember:

```
> scipy.info('optimize')
```

- Pedagogical documentation:
- http://docs.scipy.org/doc/scipy/reference/tutorial/optimize.html
- http://docs.scipy.org/doc/scipy/reference/optimize.html

f2py

- Many things are fast with Numpy
- Iterative algorithms over **array values** are slow
- You can import Fortran functions and subroutines with f2py
- You could also call external fortran programs with

```
> subprocess.call(<program>, shell=True)
```

  - but data exchange has to be through files (slower)

- f2py finds your fortran compiler. Works with gfortran, ifort,...
- f2py creates a module you can import in python
- As simple as:
- `$ f2py -c <file> -m <module>`
  - Tip: first compile it to check it works

f2py II

```
module funcs
implicit none
contains
function f1(x,y)
  real,intent(in):: x,y
  real:: f1
  f1=x+y**2
end function f1

function f2(x,y)
  real,intent(in):: x,y
  real, dimension(3):: f2
  f2(1)=x+y**2
  f2(2)=sin(x*y)
  f2(3)=2*x-y
end function f2
end module
```

```
$ f2py -c test.f90 -m test
```

- go to ipython:

```
> import test
> test.funcs.f1(1,2)
5.0
> test.funcs.f2(1,2)
array([ 5., 0.90929741, 0.],
dtype=float32)
```

f2py III

Using ipython magicfunctions:

```
sudo pip3 install -U fortran-magic
```

Useful for performing long array operations

```
In [5]: %load_ext fortranmagic

In [6]: %%fortran
        subroutine f1(x, y, z)
            real, intent(in) :: x,y
            real, intent(out) :: z

            z = sin(x+y)

        end subroutine f1

In [7]: f1(1.0, 2.1415)

Out[7]: 9.26574066397734e-05
```

Big data, big memory

- Numpy arrays are meant to live in memory
- If that is not possible:
  - Use op= operations (they use half the memory):
    - `p *=alpha` is better than `p = p*alpha`
  - Use `scipy.sparse` matrices
    - http://docs.scipy.org/doc/scipy/reference/sparse.html
  - Use `PyTable` to store (compressed) matrices on disk
    - http://www.pytables.org/
  - Modify your algorithm to work with submatrices

Sympy: Symbolic math

- Symbolic algebra
- Analytic solution of equations
- Integration, derivation
- Polynomials
- Limits

Alternate forms:

```
(cos(x + y)).expand(trig=True)
```

$$-\sin(x)\sin(y) + \cos(x)\cos(y)$$

```
trigsimp(cos(x + y))
```

$$\cos(x+y)$$

```
(cos(x + y)).rewrite(csc, sin, sec, cos, cot, tan)
```

$$\frac{-\tan^2\left(\frac{x}{2}+\frac{y}{2}\right)+1}{\tan^2\left(\frac{x}{2}+\frac{y}{2}\right)+1}$$

```
(cos(x + y)).rewrite(sin, exp, cos, exp, tan, exp)
```

$$\frac{1}{2}e^{i(-x-y)} + \frac{1}{2}e^{i(x+y)}$$

```
>>> integ = Integral(sin(x**2), x)
>>> integ
⌠
⎮  ⎛ 2⎞
⎮ sin⎝x ⎠ dx
⌡
>>> integ.doit()
                    ⎛√2⋅x⎞
3⋅√2⋅√π⋅fresnels⎜────⎟⋅Γ(3/4)
                    ⎝ √π ⎠
──────────────────────────
          8⋅Γ(7/4)
```

http://sympy.org/en/index.htm

Add-ons

Add ons: Biopython

Biopython

```
from Bio.PDB import *

p=PDBParser(PERMISSIVE=1)

s=p.get_structure('1OJR', filename)
```

Print out the coordinates of all CA atoms with B factor > 50:

```
for model in s.get_list():
  for chain in model.get_list():
    for residue in chain.get_list():
      if residue.has_id("CA"):
        ca=residue["CA"]
        if ca.get_bfactor()>50.0:
          print ca.get_coord()
```

http://biopython.org

Add ons: Machine learning and statistics

- Basic statistics in scipy.stats
  - Tutorial: http://docs.scipy.org/doc/scipy/reference/tutorial/stats.html
  - Reference: http://docs.scipy.org/doc/scipy/reference/stats.html
- Machine learning with sklearn
  - http://scikit-learn.org/stable/
  - Choosing the method: http://scikit-learn.org/stable/tutorial/machine_learning_map/
- More algorithms (and a textbook) with AstroML
  - http://www.astroml.org/

Add ons: itertools

```
> import itertools
> perms = itertools.permutations('ABC', 3)
> list(perms)
[('A', 'B', 'C'),
 ('A', 'C', 'B'),
 ('B', 'A', 'C'),
 ('B', 'C', 'A'),
 ('C', 'A', 'B'),
 ('C', 'B', 'A')]
> list(itertools.combinations('ABC',2))
[('A', 'B'), ('A', 'C'), ('B', 'C')]
```

Add ons: active papers

ActivePapers is a framework for doing and publishing reproducible research. An ActivePaper is a file that contains code (Python modules and scripts) and data (HDF5 datasets), plus the dependency information between all these pieces. You can change a script and re-run all the computations that depend on it, for example. Once your project is finished, you can publish the ActivePaper as supplementary material to your standard paper.

http://khinsen.wordpress.com/2013/09/27/activepapers-for-python/

Optimization and debugging

Optimization

- “Premature optimization is the root of all evil” Knuth
- `%timeit a=np.random.random(100000)`
- ```
  a=np.random.random(100000)
  n_dim=3
  %%timeit
  x=np.zeros(shape=(100000,n_dim),order='F')
  for j in range(0,n_dim):
      x[:,j]=a*j
  ```
- Evaluated in a separate enviroment
  ```

Exceptions and errors

Although the language is interpreted there are some syntax errors that prevent execution:

```
def safe_divide_1(x, y)

File"/home/ramon/python/prova.py",
   line 1
     def safe_divide_1(x, y)
                              ^
SyntaxError: invalid syntax
```

Exceptions leave a trace easy to follow.

Easy debugging with

%pdb

%debug

pdb: python debugger

```
In [1]: pdb
Automatic pdb calling has been turned ON

In [4]: run foo.py
NameError: name 'b' is not defined
> /home/ramon/python/foo.py(2)<module>()
      1 a = 3
----> 2 print(b)

ipdb> ?
```

pdb: python debugger

```
In [9]: run foo.py
---------------------------------------------------------------------------
NameError                                 Traceback (most recent call last)
/home/ramon/python/foo.py in <module>()
      1 a = 3
----> 2 print(b)

NameError: name 'b' is not defined

In [10]: %debug
> /home/ramon/python/foo.py(2)<module>()
      1 a = 3
----> 2 print(b)
ipdb>
```

Numba

- Numba compiles in a virtual machine.
- Developped by Continuum analytics, so easiest install from conda.
- `$ conda install numba`

Cython

- An extension to python that generates C code that can be compiled
- Available in most linux distributions
- Fortran programmers can use f2py, available in scipy.
- See also:
- https://jakevdp.github.io/blog/2013/06/15/numba-vs-cython-take-2/

Other alternatives

- Use Julia
  - A different language
  - Close in syntax to Python
